Lake Michigan Sanitary Association—At the annual meeting of the Lake Michigan Sanitary Association in Milwaukee, November 26 resolutions were adopted petitioning Congress to make an exhaustive investigation of the Great Lakes, supporting the enactment by Congress of the bill carrying $300 000, including $25,000 for Lake Michigan, now under construction, for the purpose of making investigation of the extent and of the injury inflicted by the pollution of the lake water on the health of the population of the lake region, and endorsing the report on sewage disposal submitted to the authorities of Milwaukee, and the efforts of the present administration of the city of Milwaukee to carry out the recommendations embodied in the report, and recommending its study and consideration by the health officers of the several cities on the Great Lakes

Personal—The Buchanan Medal, awarded by the Royal Society to Col William C Gorgas, M C, U S Army, chief sanitary officer of the Isthmian Canal Zone, was presented at a meeting of the society, November 30, and was accepted on behalf of Colonel Gorgas by the private secretary of the United States Ambassador ——Colonel Gorgas and staff sailed for Guayaquil Ecuador, December 4 where he will make an investigation of the sanitary condition of the port, at the request of the government of Ecuador ——Dr Carl Alsberg, a chemist in the Bureau of Drugs and Plants, has been appointed *chief of the board of chemistry of the Department of Agriculture*, a position which has remained vacant since the resignation several months ago of Dr Harvey W Wiley ——Dr Paul Preble, U S P H Service, has been directed to investigate the prevalence of tuberculosis, trachoma, small pox and other contagious diseases among the Indians of North and South Dakota ——Major Clyde S Ford, M C, U S Army, on duty at the American United States Embassy, Constantinople, is working energetically at the cholera camp at San Stefano

FOREIGN

Hygiene Exposition at Genoa, Italy—The international hygiene and maritime exposition to be held at Genoa, Italy, March 1914 is to have an Italian colonial exhibit which is to be made a special feature of the exposition from the historical and medical standpoints

Personal.—The Norwegian physician Dr C Frellsen, who has been a practitioner at Antwerp Holland, since 1877, recently returned to Christiania to live. His friends at Antwerp presented him with a purse of $5 000 when he left and gave him a souvenir address printed at the Plantin press which dates from the sixteenth century

LONDON LETTER

(From Our Regular Correspondent)

London, Nov 23 1912

The National Insurance Act The Crisis in the Profession at Hand

The special representative meeting of the British Medical Association has been discussing during the week the most momentous question that has ever been presented to the profession whether to decline service under the national insurance act or to come to some compromise with the government As stated in a previous letter, the great majority of the divisions of the association passed resolutions against working the act At this meeting a prolonged and animated discussion took place which as in previous meetings of the representatives showed the existence of two parties both indeed hostile to the act but one more uncompromising than the other After some discussion it was decided to select from the agenda the following resolution of the Bradford division as the one best suited for bringing the question to the point "That in the opinion of this representative meeting the regulations issued by the insurance commissioners and the latest proposals of the Chancellor of the Exchequer (described in my previous letter) are unworkable, derogatory to the profession and a positive danger to national health As a consequence the medical profession declines to undertake service under the act and regulations as at present constituted" It was suggested that the words "a positive danger to national health" were too strong and should be deleted This was done and the resolution was carried by an overwhelming majority An amendment to substitute the word "unsatisfactory" for "unworkable and derogatory to the profession" as being unnecessarily provocative was lost A discussion was then taken on a more conciliatory motion of the Norwich division "That the recent offer of the Chancellor of the Exchequer affords the British Medical Association an opportunity for conferring with him and with the commissioners as to the points on which the demands of the profession have not yet been met." After discussion the words "as to, etc," were deleted and for them were substituted the words "with a view to the settlement of the points on which the demands of the profession have not yet been met" As amended, the resolution was carried by a majority of 167 to 84 The representative of the Hereford division moved that a copy of the resolution be sent to the chancellor and that he be informed that "any further proposals of the government for meeting the grave objections of the profession shall receive the most careful consideration of the British Medical Association" –After discussion it was decided to take a card vote on this motion This revealed an extraordinary equality of divided opinion whether to enter into *negotiations or not with the government For doing so the* card vote was 9,292, against, 9,269, majority, 23 If the voting had been taken by constituencies the resolution would have been reversed by a slight majority ayes, 100, noes, 101 Ultimately it was decided to appoint five members to confer with the chancellor

HOSTILITY OF THE TRADE UNIONS TO THE PROFESSION'S DEMANDS

The executive board of the General Federation of Trade Unions has issued a statement that "The continued subordination of the general interests of the community to the financial *interests of the medical profession can be described only as* scandalous" This is a little remarkable when one considers that the policy of trade unionism in general is thus accurately described It is not so long ago since in the London dock strike the Union of Transport Workers attempted to hold up the food supplies of fourteen million people by stopping the unloading of the Thames shipping The reason for the strike was flimsy, for these workers though lowly skilled are highly paid Their leaders thought the time had come when they could dictate the terms on which transport from the docks was to be carried on But the practice of the most ruthless egoism and the preaching at the same time of altruism for other people has always characterized the labor leaders The following resolution has been sent to the Chancellor of the Exchequer

The executive board of the General Federation of Trade Unions representing an affiliation of 105 trade unions, emphatically protests against the continued attempts of the medical profession to exploit the national insurance act and to avoid any semblance of control by the insured persons or their representatives The board urges the pressing need for an immediate settlement of the dispute concerning medical attendance by the creation of a state medical service or by the transference to the credit of the approved societies of those amounts last offered for medical attendance and medicine, in order that neither the approved societies nor their members may suffer any further disadvantage or handicap through the refusal of the medical profession to accept the more than generous terms now offered"

A Tribute to American Medicine

In a letter to the *Lancet*, Mr Arbuthnot Lane has expressed his gratification at the recognition of Carrel's magnificent work by the bestowal of the Nobel prize and incidentally paid a warm tribute to American medicine To him the career of Carrel Frenchman though he may be by birth, is typical of the intense desire to progress which pervades America The American man of science devotes himself heart and soul to his work feeling that merit is the only road to success, and that if he does succeed he commands the love, esteem and admiration of his fellows in a manner that does not exist in the more complicated conditions of the Old World The more Mr Lane sees of America the more he is impressed by the determination of the members of its medical profession to occupy the van of progress by rendering themselves familiar with any advance in science and by combining among themselves to ensure a very high and progressive standard of knowledge Mr Lane concludes "America has every reason to be proud of its capacity to present to the moving spirits of the world a soil in which they can grow with uninterrupted and stimulated vigor, and in which merit and genius receive a recognition unequaled, I believe, elsewhere Carrel is a typical product of these conditions"

The Origin of Life

The recent address at the British Association by the president Professor Schafer, on the origin of life (abstracted in a previous letter) has naturally aroused criticism in scientific circles The veteran naturalist, Dr Alfred Russell Wallace, the codiscoverer with Darwin of natural selection, concludes an article on the subject as follows "In the whole vast world of life, in all its myriad forms, whether we examine the lowest types possessed of the simplest characteristics of life, or whether we examine the higher forms of life, we follow the process of growth from a single cell up to the completed organism, even to that of a living moving, feeling, thinking, reasoning being such as man himself, we find everything a stupendous, unceasing series of continuous motions of the gases fluids and solids of which the body consists These motions are strictly coordinated, and, taken together with the requisite directing and organizing forces, imply the presence of some active mind power The assertion that life is due to chemical and mechanical processes alone is quite unjustified Neither the probability of such an origin nor even its possibility has been supported by anything which can be termed scientific facts or logical reasoning"

Discussing the same question at the Chemical Society of London in an address on "The Discovery of Radio Activity Its Influence on the Course of Physical Science," Sir Oliver Lodge remarked that the great thing to avoid in science was negations Let them make and substantiate positive assertions It might be impossible to construct living matter out of artificially combined materials, but the attempt was quite legitimate, and no one could say that it would never be successful In so far as life demanded energy for its peculiar manifestations, a possible source of such energy might be suggested in the phenomenon of radio activity In the physical universe our power was limited to the movement of matter, all that happened after that was due to the properties of matter and of its ethereal environment If potentially living matter was ever artificially produced by placing things in juxtaposition and bringing natural physical resources to bear on the assemblage, which was all that we could do, then it might become alive But if this last step were taken it would be because something beyond matter, and outside the region of physics and chemistry, had stepped in and utilized the material aggregate provided, in the same way, presumably, as that in which it now steps in and utilizes the material provided, say, in an egg or a seed

The Government Inquiry Into Nostrums. The Failure of a Prosecution

At the last sitting of the committee of the House of Commons appointed to inquire into the present state of the law regarding the advertisement and sale of nostrums the important question arose as to the power under the existing law to prosecute venders Professor Dixon gave evidence to the effect that if the law were put into action the evil might be considerably mitigated as the Merchandise Act gave power to public authorities to prosecute in case of fraudulent misrepresentation, and he referred to a prosecution by the Liverpool corporation as an example When Dr E W Hope, health officer of Liverpool, was communicated with, however, he stated that in 1907 information was laid against a firm of pharmacists as the venders of a patent medicine (not their own preparation) on the ground that a false representation was made on the label The case was withdrawn, as no evidence of guilty knowledge on the part of the venders could be brought forward and the pharmacists were awarded $20 costs Further analyses had been made of patent medicines, but no local proceedings had been taken since

The Pasteurization of Milk Criticized

Dr Ralph Vincent, a pediatrist who has done a good deal of research work, seriously criticizes the prevalent practice of sterilizing and pasteurizing milk He states that as the result of bacteriologic work, experiments on animals and an extensive clinical experience, to treat milk by these methods is to destroy the very germ (*Streptococcus lacticus*) on which the wholesome state of the milk depends, and in the absence of which other putrefactive germs have full play, producing acute poisonous effects in the bowel of the infant, leading frequently to a fatal result especially during a hot season Vincent's remedy is a simple one viz never use anything but raw milk, cooled in the refrigerator immediately after milking to a temperature of about 35 F and sent out in receptacles fitted with an insulating air wall" so that there is no rise of temperature in its transit to the house of the consumer This method would lead to a slightly increased cost but it is asserted that this need not be large

Libel Action by a Nostrum Vender Against the British Medical Association

The publication of the book "Secret Remedies What They Cost and What They Contain" by the British Medical Association has naturally been much resented by the nostrum venders who, however, have not thought it wise to attempt any legal action At last, Stevens & Co, selling a nostrum as a cure for consumption has brought an action for damages This case, which occupied the attention of the court for a week, is most important as it shows the danger to which any one who endeavors to expose quackery is exposed under the present state of the law, in spite of overwhelming medical evidence of the justice of the strictures passed After referring in general terms to fictitious claims for inert nostrums the book goes on to say 'It is the victim's money that is wanted, therefore the price is fixed high and the advertisements written up to it Although Stevens is so engagingly candid about his rivals he follows the plan of sending one letter after another to any sufferer whose name he may have obtained, a system which seems to have been invented in America, it is certainly cheaper than bold advertisement in the newspapers, and is apparently more satisfactory, as it enables the vender to give individual attention to the depth of his correspondent's pocket The farce of revealing a formula by such fancy names as these is one of the oldest dodges of the quack medicine man and no such names as 'umckaloabo' and 'chijitse' appear in any available work of reference in pharmacy" Later the following description was given Stevens, C H, the proprietor of a remedy for consumption which has been put on the market in South Africa and England under the name of Sacco and later in South Africa as Lungsava, the recipe for which is stated to have been long in use among the Kaffirs and Zulus Stevens has acquired a number of testimonials from medical men who must now regret their precipitate action He is now in England on a new campaign" The remedy was described as "a clear red liquid containing in 100 fluid parts 21 3 parts of alcohol 1 8 of glycerin and 4 parts of solid substance This solid substance agreed in all respects with the solids of decoction of krameria or a mixture of this with a little tincture of kino"

For the plaintiff, Mr E M Holmes, curator of the Pharmaceutical Society of Great Britain and formerly lecturer for the society gave evidence that the plaintiff had submitted to him for examination two substances—a plant called chijitse, which he recognized as belonging to the natural order *Geraniaceae* and a root, called umckaloabo which, from microscopic examination he believed belonged to the *Polygonaceae* family Some analytical chemists also gave evidence that they had examined the plaintiff's remedy and found that it did not contain either krameria or kino Several doctors of no eminence whatever one of whom described himself as the "author of a number of letters to the *Lancet*,' stated that they had found the nostrum beneficial Stevens himself gave evidence that his mixture was made from the plant mentioned above which grew in South Africa and was used by the natives in the treatment of consumption and also from the root mentioned When Secret Remedies" was published he was doing a large business—$21,000 a year, after its publication his receipts dropped to $14.500 He had sent letters to thousands of physicians and had received thousands of letters from them, though often with requests not to publish their names On cross examination he admitted that the statement in one of his advertisements that he had gone through unexplored country in Africa and spent thousands of pounds to get the remedy was "exaggerated ' it was written by an advertising agent and he did not read it carefully For the defense a number of eminent specialists, Dr Theodore Acland, Sir Douglas Powell Dr Arthur Latham and others were called and stated that there was no evidence whatever that Stevens' mixture had any curative properties or contained any active principle capable of influencing consumption

Mr Justice Pickford in summing up said that the case was important, because if the plaintiff had been wrongfully accused he was entitled to be cleared On the other hand, it was important [illegible] Brit [illegible] ical Association should have a right to [illegible] of the jury did not necessarily involve whether the remedy was good or bad. The defendants had said in effect that the plaintiff claimed in his advertisements to cure advanced cases of consumption, although he knew he could not do so. If they proved that, they were entitled to a verdict. In his advertisements the plaintiff had claimed to cure every case of consumption. He also stated that he returned to England from South Africa "to prove his work to the satisfaction of the British government." This was inaccurate, because he returned to start a commercial enterprise. In another advertisement he said "It cost me many years of ceaseless toil to bring the remedy to its present state of perfection." He had given no evidence to that effect. In another advertisement he invited persons suffering from consumption to such an extent as "to consume all except the soul and the bones" to see him. Persons in the last stage would naturally pay anything. Did he honestly believe that he had a remedy which would then be effective? None of the physicians called by him had said anything which justified his claim to cure advanced cases. If he made claims which he knew were improper, then the defendants had proved what they said. If it was not quite true the defendants might have to pay damages. The jury disagreed and was discharged.

It is a melancholy fact that no matter how preposterous the claims for a nostrum may be physicians can always be found to swear that it has proved beneficial in their experience, but these are never men of any professional eminence. They are quite unknown to the general profession until they appear in the witness box.

PARIS LETTER

(From Our Regular Correspondent)

Paris, Nov. 15, 1912.

Population Statistics

The population of France during the first semester of 1912 shows in place of the excess of 18,279 deaths recorded during the first six months of 1911, an excess of 14,172 births. This is caused by a decrease in the death rate, for the birth rate has continued to decrease in spite of an increase in the marriage rate.

Formation of an Army Morphologic Laboratory

A laboratory of morphology has been founded at the Palais des Invalides. It is intended to permit the army to benefit by recent work on human morphology and to make use of soldiers for the study of anthropologic types.

Dr. Monprofit and the Balkan War

Dr. Monprofit, professor of clinical surgery at the Ecole préparatoire de médecine d'Angers has been invited by the Greek government to go to Greece to organize a sanitary service in the military hospitals. He has accepted on condition that his sojourn in Greece shall be only for a few weeks and that he shall remain free to return to France if European complications arise.

Foundation of a Municipal Museum of Hygiene

The city of Paris has just founded a museum of hygiene which includes a library of seven sections devoted to urban hygiene, the hygiene of dwellings, prophylaxis, the hygiene of foods, group hygiene, hygiene of transportation and social hygiene.

One Hundred and Fiftieth Anniversary of the National Veterinary School of Lyons

The one hundred and fiftieth anniversary of the foundation of the national veterinary school of Lyons has just been celebrated in that city. It is the oldest in France and perhaps in the entire world.

The Foundation of the International Bureau of Foodstuffs

As I have mentioned in a previous letter (The Journal, Nov. 2, 1912, p. 1637) the official delegates of the various governments represented at the international congress for the investigation of methods of analysis have decided on the creation of a permanent international bureau of analyses of foodstuffs, to be located in Paris, in recognition of the leading rôle taken by the French in the combat against adulteration of foodstuffs.

Unhealthful Houses in Paris

At the last meeting of the Société de statistique, M. Juillerat explained the working of the bureau which has in charge the sanitary condition of the houses of Paris. Since Jan. 1, 1894, account has been kept of the number of deaths from contagious diseases, especially pulmonary tuberculosis, in each house in Paris. In 1904, ten years after the records had been started, an abstract of the records was made which showed the distribution of tuberculosis in the houses. This showed that 38 per cent. of the total number of deaths had occurred in 5,263 houses. Certain sections and streets were responsible for two or three times as many deaths as occurred in the rest of the city. The officials decided then to employ means which the law of Feb. 15, 1902, had authorized for the protection of the public health, in an attempt to clean up those houses which were the active foci of tuberculosis and to make them healthful. The chief fault was the darkness of the living rooms. Up to 1908, the number of deaths from tuberculosis had been increasing. In 1907 and 1908 a total of 10,262 was reached. March 1, 1909, 549 houses, a little more than one tenth of the tuberculous houses, had been improved by having airless and dark rooms abolished. In 1909 the death rate from tuberculosis fell to 9,714. March 1, 1910, the number of houses made sanitary was 886 and the mortality fell to 9,449. March 1, 1911, 1,132 houses had been overhauled and the mortality had fallen to 9,371. This is real progress, and ought to justify the conclusion that the work of the bureau is responsible for the good results. Dr. Juillerat believes that the same system may be applied to other diseases, especially cancer, which seems to be similar as far as houses are concerned to tuberculosis, since one tenth of the deaths from cancer in the past five years have occurred in houses classed as tuberculous.

Responsibility of the Surgeon

A patient entered the Bichat hospital in the service of Dr. Lecène to be operated on for appendicitis. He was placed on the operating table, anesthetized with chloroform and washed with soap, alcohol and ether. These substances were then wiped off with compresses. At this moment, having perceived an acne papule which later might cause infection, Dr. Lecène asked for a thermocautery. In burning the papule he caused a severe accident, for some alcohol which remained blazed up, severely burning the patient. Several months later Dr. Lecène and the Assistance Publique were sued for 60,000 francs ($12,000). The tribunal named three experts, Professors Pozzi, Reclus and Duval, who decided that there was no professional fault. The burn had been caused by pure accident, led up to by the unsual conformation of the patient. The ether and the alcohol had been wiped away with dry compresses according to custom, but a deformity of the hip of the patient, caused by hip joint disease from which he had suffered when young, had caused a little alcohol to remain in the inguinal fold, which was unusually deep; besides, the patient did not lie flat on the table because the loins owing to ankylosis were unusually prominent, and the alcohol ran under his back and was absorbed by the linen which had been placed there. Notwithstanding the opinion of the experts, the court decided that though there may not have been professional fault there was at least negligence. Far from agreeing that the deformity of the patient justified an interpretation of the injury as accidental, the court decided that the surgeon, who must have noticed the deformity and who ought to have paid special attention to it, ought not to have let the thermocautery touch the patient until he was sure that no trace of alcohol remained on any part of the body, especially in the unusually deep inguinal fold, and under the back. The Assistance Publique was freed from blame, but Dr. Lecène was ordered to give the patient 15,000 francs ($3,000) damages.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, Nov. 15, 1912.

Personal

November 19, Professor Czerny, the well known Heidelberg surgeon, celebrates his seventieth birthday. He was born in Austria and studied medicine at Vienna. At first he devoted himself to ophthalmology, then he became assistant of Oppolzer and in 1868 assistant of Billroth. In August 1870, as Billroth's assistant, he went as volunteer to the Franco-Prussian War and distinguished himself mainly in the management of the hospital at Weisenburg. In 1871 he became connected with the faculty at Vienna, but the same year was called to Freiburg as director of the surgical clinic. In 1877 he became successor of Gustav Simon, director of the surgical clinic at Heidelberg. In 1906 he resigned his office of surgical instructor in order to devote himself completely to the foundation and management of the Heidelberg institute for cancer research.

Prof. A. Czerny of Strassburg, cousin of the Heidelberg surgeon, has received a call to the position of director of the Berlin pediatric clinic, as successor of Heubner On the list of those proposed for the appointment were the names of Professor Finkelstein of Berlin and Professor Salge of Freiburg, both pupils of Heubner According to all indications, Czerny will accept the position

At the request of the faculty, Dr Grotjahn has accepted a position as instructor in social hygiene, in this way the professorship of social medicine and hygiene, which is vacant as the result of the appointment of Kirchner as ministerial director, will at least be partly filled

Professor Wessely is temporarily in charge of the Würzburg eye clinic, whose director, Professor Hess, as I have already reported, has gone to Munich

Professor Kretz, director of the Würzburg pathologic institute, contemplates resigning his position

The title of "Excellency" has been conferred on Prof von Angerer, the well known Munich surgeon and private physician to the prince regent of Bavaria In Bavaria this distinction is conferred on medical men less frequently than in Prussia Prof von Leube is the only other physician in Bavaria who holds this title

Advertisements on Wrapping Paper Used by Pharmacists

Attention has been repeatedly called by physicians to the evils connected with the practice of having advertisements printed on the paper used by pharmacists and druggists in wrapping their goods These wrappers are, to a large extent, supplied without charge by manufacturers of medicines, food preparations, etc., and are covered with printed commendations of their product In this way they secure efficacious advertising before the public, and the pharmacists and druggists are willing to lend a helping hand as accomplices, because in this manner they get the wrappers free Physicians are interested in the elimination of this evil, as the public is led by such advertising to self treatment After attention was called to this fact at the last year's *Aerztetag*, as I reported at that time, the *Deutsche medizinische Wochenschrift* took an especially strong stand against this evil Fortunately, the board of directors of the German Pharmaceutic Association has recommended to its members not to use any more such wrapping paper Recently also the society of drug manufacturers has recommended similar abstention to its members In the resolutions adopted it was also advised that with pharmaceutic preparations there should not be included explicit advice as to self treatment, physician's reports, physicians' statements as to the results of the treatment, and testimonials [A fatality from this cause has recently been reported in Germany The purchaser took the medicine according to the directions found on the wrapper around the bottle, which were in the advertisement of an entirely different remedy]

Russian Students

As I reported some time ago, the medical students of Munich took strict precautions against the overcrowding of the local clinics with Russian students, especially undesirable ones Recently a St Petersburg daily newspaper harshly criticized its countrymen as revolutionary and lacking in regard for the most elementary requirements of decency Following this, the Berlin *Vossische Zeitung* asked a number of local professors, among them Hertwig, Hildebrand and Waldeyer, to express their opinion Almost all directly contradicted the insulting statements of the Russian newspaper Hertwig also states that Russian medical students in general are diligent, and that he knows of no misconduct on their part So far as the treatment of native students by the Russians is concerned no complaints worth mentioning have come to his knowledge He says that the German student regards it as an honor for a large university to attract foreign students, and thus to bring recognition of German culture also outside of its own empire

Reform in the Advertising of Medicinal Articles

In a similar manner as by the control of advertising of remedies in the medical press and by the rejection of objectionable advertisements (in regard to which I informed you in my last letter) the medical press will suppress the advertising evil which is carried on by the distribution of special reprints of articles on therapeutics It is found that manufacturers of therapeutic products distribute special reprints in which the sections giving unfavorable effects of the described remedy are suppressed, while, on the other hand, statements in favor of the product are made specially conspicuous Further, favorable reports on remedies are distributed after the statements have been recalled as experience has modified the first impressions The association of the German medical press therefore passed resolutions at its last meeting declaring that special reprints must be an unchanged copy of the original work Individual portions must not be made conspicuous for the purpose of advertising, and it is not allowed to make additions or omit certain parts The reprints supplied to a certain firm may be distributed only with the consent of the author, at first only to the end of the third year following the publication For the further distribution a new consent of the author is necessary An industrial firm may be furnished with a supply of special reprints in regard to a remedy only on the manufacturer agreeing not to distribute such reprints to the laity It remains to be seen how authors, editors and the chemical manufacturing firms will adapt themselves to these requirements

Instructions in Legal Medicine for the Police

Professor Ziemke of Kiel has established a course of medicolegal instruction for the local police to instruct them in medicolegal questions which must be considered on discovery of crime

Discreditable Remuneration in Contract Practice

A publication of the medical officers of the insurance societies in one of the larger Bavarian cities shows how just is the complaint of physicians in regard to the insufficient compensation from the Krankenkassen Of the total appropriation of 322,507 marks for the first half of 1912, for physicians, medicines and remedies, and sick benefits, physicians received only 19,567, that is 6 07 per cent The expense of management of the eight societies in the contract (one local Krankenkasse, four trade Krankenkassen and three free aid societies) will probably be not much lower! The most busily engaged physician received for each individual case (not for the individual service) for half a year 1 73 marks (43¼ cents) In this are included visits up to a distance of two kilometers (a mile and a quarter) More money was paid out to dentists than for special surgical and obstetric services, and for visits more than two kilometers distant

The city street railway company at Munich has announced that positions for four medical officers were open The total amount appropriated for these four positions is 3,600 marks, or 900 marks for each ($225), which is less than a street car conductor receives For this the medical officer will have to examine each man for the acuteness of vision, the sense of color, hearing, nervous system, etc., and give his professional judgment as regards the applications of the sick for leave of absence and stay in the country, and take care of the necessary yearly examination of the railway employees as well as the workmen employed in the varnishing department However, as a sufficient number of physicians have applied, who have not calculated any further or who have not asked regarding the salary, and as also the organized profession has not expressed any opinion on the subject, the city street railway will get its cheap help

The Medical Member of the Berlin City Council

A salaried city medical councilor with the function of a regular member of the city council was authorized at the last session of the common council of the city of Berlin The salary is at first to be 15,000 marks ($3,750), which shall be increased after three years to 18,000 marks ($4,500) (This important innovation was discussed in the Berlin Letter, November 9, p 1730)

VIENNA LETTER

(From Our Regular Correspondent)

Vienna, Nov 20, 1912

Sixth International Congress for General and Medical Electrology and Radiology

This congress, held in Prague during the first week of November, was attended by about 700 members About 130 papers were read. It was impossible to exclude political and racial enmities from even this purely scientific meeting, for Prague is the hotbed of our deplorable political difficulties Therefore German scientists were ready to boycott the congress, but at the last moment a public clash was averted It was not the fault of those who had charge of the meeting that political feeling was exhibited The members were welcomed by the government and the municipality and the social entertainments were of the customary types in such instances Of the many interesting papers the following are worthy of notice Professor Stoklasa of Prague spoke on the Influence of Radio Active Substances on the Development of Plants" He had worked with pitchblende containing in 1 kg only 0 000136 gm of radium He used from 0.5 to 1 gm (7½ to 15 grains) of pitchblende enclosed in a glass tube and placed in the flower pots By these means he could increase the productivity of the plants by from 50 to 70 per cent If radio active water be used, the best results are obtained with water containing 600 Mache units, as the plant embryo is awakened more quickly and the semen begins to develop with greater energy In some instances the gain was 100 per cent compared with ordinary water It was found that photosynthesis of the carbohydrates in the cells with chlorophyl is increased by radio activity This might be used in future farms on a scientific base Similar experiments were conducted by Professor Doumer of Lille, France He used emanation, plants in this gas were made to grow more quickly, all the other conditions (temperature, humidity) being equal The growth of wheat especially was increased

Professor Mezernickyi of St Petersburg, read an instructive paper on "Chemical Actions of Radium Emanation" The chief result of his experiments is the fact that purin bases are dissociated by emanation He therefore emphasizes the hypothesis of His, that uric acid can be dissociated by radium, this was formerly doubted by many authors Uric acid is broken up into carbon dioxid and ammonia He further could show that 29 mg of sodium urate were dissociated by radium emanation within twelve days Bertolotti of Turin, Italy, has examined various radio active substances from a therapeutic point of view He found that actinium and mesothorium are even more energetic in destroying living tissues than radium itself Ghilarducci of Rome has treated diabetes mellitus with emanation He claims that in several cases this resulted in a disappearance of sugar from the urine The use of radio active waters and emanation in the Bohemian baths was described in a paper by Drs Pelc and Trema They have examined the springs of all the Bohemian spas, including Karlsbad and Joachimsthal, and gave in their paper details relating to the inhalation and drinking cure of the various places, as well as descriptions of the bathing establishments

Dr Manabe of Tokio described the Japanese radio active baths The Japanese make a large hole in the ground where radio active waters appear and the baths are taken there and *then This prevents the loss of emanation so frequent in the* European baths

The Surgical Use of Radio Activity" was the title of a paper by Professor Sticker of Berlin He employs radium combined with mesothorium for malignant growths, accessible to this treatment with satisfactory results A paper by Messrs Degrais, Wickham and Slavik of Paris dealt with the same subject The authors have been working on the *treatment of* cancer by radium for four years They assert that it is possible to benefit also internal cancer by permanent application of radium in tubes

The influence of alkalies in the conductivity of the blood was investigated by Professor Trunecek of Prague He has found that electricity is conducted in the blood not by the water or by its organic substances but simply by its mineral salts The latter are dissociated by the electric current into the basic and acid components which are the real carriers of electricity Trunecek has made a serum out of the salts contained in the normal blood plasma which, he says, are useful in cases of hypertension and arteriosclerosis or when the viscosity of the blood has increased owing to the accumulation of acid products of metabolism The application of high frequency high tension currents was shown and described by Professor Etcheverria of Santiago Chile He has invented an apparatus permitting application *of the strongest currents on the human body with impunity He uses this method of treatment in* certain psychoses and brain diseases and reports good results with this novel method Dr Bonnefoy of Cannes states that his observations on the physiologic action of high frequency currents have convinced him of their calming action on the circulation although the rapidity of the blood stream is increased and the peripheral warmth is raised

A remarkable paper which caused much discussion and criticism was read by Cirera Salse of Barcelona, who reported that he had cured appendicitis by galvanization and electrolysis He also pointed out that electrolysis has a great future in the treatment of exudations and inflammations of the pelvic organs In another paper on the treatment of malignant growths Wickham of Paris gave details of his method of attacking the newly formed tissue the essentials being the application of the radium at the base and around the periphery of the growth and the use of large doses so that destruction of cells is surely obtained, it must be kept in mind *that a* weak application cannot be compensated or strengthened by the duration of the exposure to the radium It is advisable to influence all parts of the tumor in an equally strong degree.

Professor Becquerel read a paper on "Radio Activity and Biology" Although at first it was thought that all life was accompanied by radio activity, exact investigations have proved that radio activity is rather detrimental to life, some rays even being directly fatal to cells Thus the *x* rays, consisting of positively charged particles and possessing a velocity of 20,000 km per second, are most abiotic, while the beta rays, *consisting of negative particles (like the cathode rays)* and having the highest penetrative power, are about equally dangerous to life Their chemical action is similar to that of the ultraviolet rays of very short undulations Interesting data were found by Strutt in his investigations into the age of life in the universe He has found that a mineral contains the more helium the older it is The same holds good of fossils *from various geologic periods The alluvial deposits on the* rocks of Ontario enabled the scientist to reckon out, under these suppositions, the age of the first oceans inhabited by living organisms as over six hundred millions of years Since then, evolution had time to take place in the course of the geologic periods

Although the congress was intended not only for medical men but also for all those interested in electricity (numerous papers being read on wireless telegraphy and on problems of electric traction and light), the majority of the members belonged to our profession It was a success as it was possible to attract the attention of the whole civilized world, and at the final meeting it was decided to hold another congress in two years The meeting place will be chosen next year

Definite Regulation of the Relations Between Dentists and Technicians

The long conflict between the surgeon dentists and the technician-dentists will soon be a matter of the past According to a bill recently proposed by the government, in the future only graduated physicians will be entitled to practice dentistry in Austria The technical assistants will be permitted to work only in cooperation with or as subordinates to physicians The profession of technical dentists (*Zahntechniker*) will be *allowed to die out The law makes certain temporary* concessions to those technical dentists who at present are practicing in this country under the technical license Thus they will be entitled to remove or to fill carious teeth if it is absolutely necessary in the process of substituting a denture, bridge or crown work, but they must not use an anesthetic or do anything that requires profounder medical knowledge Medical men protest vehemently against this permission of surgical dentistry to non medical men, while the technicians, on the other hand, demand that for the future all technicians should be able to obtain an extension of license by passing certain examinations in order to be permitted to do minor surgery in the mouth The bill will put an end to the bitter conflict Already on these grounds a few years' charges against technicians have been dismissed

Professor von Pirquet on Diseases of Childhood in School

The well known specialist for diseases of children recently read before the Society for Hygiene of the School an interesting paper dealing with the diseases of school children He finds that school diseases can be classified under one of the following heads infectious diseases, disturbances of development of the body and degeneration The surroundings are frequently responsible for disturbance of development Well fed children grow more rapidly and better than underfed children Instruction in hygienic principles is of the utmost importance. The chief object of the Society for Hygiene of the School must be to make public the results of the united experiences of parents *teachers and school physicians in order that a healthy and* strong generation of children may grow up to be healthy citizens

Improved Facilities for Veterinary Surgeons

Owing to the boycott organized about a year ago by veterinary students against the veterinary school, the government has found that it is no longer possible to neglect the just demands of the students Just now veterinary surgeons are in more demand than ever before, partly on account of the threatening war Thus the government has consented to admit veterinary surgeons into the army under conditions similar to those open for physicians The school will be endowed with sufficient funds for obtaining ample material for dissecting work, scholarships will be instituted in the school and a *completely new equipment with sufficient space for study is being* added to the veterinary hospital existing at present All endeavors are being made to obtain first class teachers for the students.

Miscellany

Disinfection of Schoolrooms.—Better knowledge of the manner in which infectious diseases are transmitted has shown the importance of contact infection. As the ordinary communicable diseases are more prevalent among children, especially school children, the importance of adopting measures to minimize the dangers of contact infection among them is apparent. In addition to the medical inspection of school children and the isolation of suspects or carriers, the frequent disinfection of schoolrooms is an important preventive of the dissemination of infectious or contagious diseases. At the Fifteenth International Congress on Hygiene and Demography, J. T. Ainslie Walker read a paper on the routine disinfection of schools, which, after giving the results of investigations concerning the rôle of school children in the transmission of infectious diseases to other members of the family, he summarizes as follows: The presence of a certain proportion of infectious children is admittedly unavoidable. These infectious children must diffuse a certain amount of infective material, the removal of which by means of frequent and thorough washing of schoolrooms and cloak rooms is, on the ground of expense, impossible, or is at least so regarded by the educational authorities. He, therefore, offers the following plan, not as a panacea, but as a reasonably efficient measure in keeping down the occurrence of infectious diseases transmitted by the contact of school children. When the school is over for the day the floor of each class room should be moistened with a disinfectant solution, such as 1 part of pure phenol to 25 parts of water, by means of an ordinary sprinkling can with fine holes, and swept in the usual manner while still damp. Desks and seats should be dusted with a cloth sprinkled with the same solution. Dry dusting and sweeping should on no account be permitted. Once a week the walls to a height of 6 or 7 feet from the floor should be moistened with the same preparation by means of a spraying machine, seats, desks, hat and cloak pegs should be treated in the same manner and all inaccessible places where dust accumulates should be thoroughly wet with the solution. Every quarter the spraying operation should be extended to include all parts of the walls and ceiling. Walker says that the evil effects of breathing dust filled with bacteria cannot be gauged solely by the actual illness occurring among students. Many minor ailments so contracted may be too mild to warrant absence from school or call for immediate treatment, and Walker regards the method of disinfection by gas or fumigation ineffective. As an argument in favor of greater precautions in disinfection of schools, he says that as children are legally forced to attend school it follows that they should be protected to as great an extent as possible from disease by the most effective practical measures we have at hand. The Journal is disposed to wonder as to the reception which would be given to this mode of disinfection. The continuous odor of phenol throughout the school building, which would perhaps be even carried home in the scholars' clothing, might arouse protest which would interfere with the carrying out of the plan.

Relation of Eugenics to Euthenics.—Of late years several nations have been viewing with alarm their rapidly diminishing birth rates. It has not been generally recognized, however, wherein the danger really lies. The fact of a decreasing population may in itself be of serious economic import, and even though the total population is being maintained or is growing on account of immigration, accession from without then means the swamping of the native stock. But immigration aside, the greatest cause for alarm is revealed on an analysis of the statistics on the decrease in the number of children born. Such analysis shows that the decrease is not proportional for the total population, but that it is greatest among those classes of society which are the more desirable, namely, the professional classes, the artisans and the so called middle classes generally. Statistics show that whereas in London the birth rate was higher sixty years ago among the classes just mentioned, fifty years later the conditions had become exactly reversed, and that the paupers, the defectives and the undesirable generally were reproducing at a greater rate than the other civic elements. The outcome of such a state of affairs without the intervention of other forces, would be easy to predict. One modifying factor exists in the differential death rate, which falls most heavily on the physically and morally unfit, but here again the statistics have shown that this factor is not sufficient as a corrective. Is not this a fertile land for eugenic search? And may the eugenist not hope to offer suggestions of value? It may be some time before we can hope to do much directly to stimulate the birth rate among the better classes, but is it not time that steps were taken to check it among the worse?—L. J. Cole in *Pop. Sc. Month.*

"Essential Nephralgia."—L. Billon contributes a long article to the *Archives Provinciales de Chirurgie* (1912, xxi, 521), on the question whether there is such a thing as essential nephralgia, that is, pain in the kidney without an essential cause. He reports two cases which apparently belonged to the category but in which the pain was finally traced to abnormal movability of the kidney or other cause, and he is convinced that patient search will reveal a cause in all such cases. He reviews the differential significance of the character and site of the pain, a history of trauma, etc., and discusses the clinical pictures of latent nephritis, perinephritis, liver and pancreas disease, etc., liable to induce pain in the kidneys, and remarks in conclusion that the results have always been fortunate in the cases of the so called essential nephralgia in which operative measures were applied, some condition was invariably found which explained the pain and which was cured by the operation.

Marriages

James A. Rusmisell, M.D., Buckhannon, W. Va., to Miss Anna L. McNutt of Sutton, W. Va., at Clarksburg, W. Va., November 21.

Frederick M. Poindexter, M.D., to Miss Florence Grace Graeter, both of Dillon, Mont., at Argenta, Mont., November 21.

Harry Glenville Tonkin, M.D., Martinsburg, W. Va., to Miss Mary Lillian Licklider, at Martinsburg, November 28.

Earl William Cauldwell, M.D., Lemont, Ill., to Miss Kathryn Smollen of Hazeldell, at Lemont, November 28.

Robert Glendenning Washburn, M.D., to Mrs. Grace Watrous Foster, both of Milwaukee, Wis., November 28.

Frank Ira Bishop, M.D., Williamstown, N. Y., to Miss Florence Morphy of Brantford, Ont., November 18.

Arthur Madison Phillips, M.D., to Miss Lynnie Susan Whitaker, both of New York City, November 27.

Harry L. Pelle, M.D., Louisville, Ky., to Miss Clara E. Wilson of Shortsville, N. Y., November 23.

Michael Albert Abrams, M.D., Baltimore, to Miss Marie Silberstein, at Baltimore, November 28.

George Earl Henton, M.D., to Miss Bertha Anna Hacker, both of Friend, Neb., November 13.

Jacob Liencester Shirley, M.D., to Miss Ethel J. Mathews, both of Dawson, Ga., November 3.

William C. F. Witte, M.D., Milwaukee, Wis., to Miss Lillian E. Barr of Chicago, November 28.

Thomas A. McGoldrick, M.D., to Miss Rita Connell, both of Brooklyn, N. Y., November 27.

John Louis Schwer, M.D., to Miss Georgia Isherwood, both of Pueblo, Colo., November 28.

Abraham Ezra Jaffin, M.D., to Miss Matilda Serge, both of Jersey City, N. J., October 8.

Charles Rehling, M.D., Fremont, Wis., to Miss Ostrander of Milwaukee, November 20.

Oliver S. Lloyd, M.D., to Miss Golda L. Pearce, both of Baltimore, November 28.

E. Agnes Scott, M.D., and Willard Brandon, both of Denver, Colo., November 10.

Morris Wenger, M.D., to Miss Tillie Ullman, both of Reading, Pa., November 28.

Deaths

Edward Curtis, M D University of Pennsylvania, Philadelphia, 1864, a member of the Medical Society of the State of New York, and American Association for the Advancement of Science, brevet captain and major U S Army, during the Civil War, one of the first to make microphotographs and astronomical photographs, who was placed in charge of the microscopic department of the Army Medical Museum after the Civil War, where he remained until his resignation in 1870, professor of materia medica and therapeutics in the College of Physicians and Surgeons, New York City, from 1873 to 1886, and thereafter professor emeritus, microscopist to the Manhattan Eye and Ear Infirmary, surgeon to the New York Eye and Ear Infirmary, president of the New York Ophthalmological Society, a trustee of the New York Dispensary and medical director of the Equitable Life Insurance Company from 1876 to 1904, died at his home in New York City, November 28, from cerebral hemorrhage, aged 74

John Dale McGill, M D University of Pennsylvania, Philadelphia, 1870, a member of the American Medical Association and Association of Military Surgeons of the United States, medical director and visiting surgeon to St Francis Hospital Jersey City, local surgeon of the Pennsylvania and Erie systems and chief surgeon of the North Jersey Street Railway Company, for several years president of the Hudson County Medical Society, for twenty six years surgeon general of New Jersey, at one time police commissioner, president of the board of finance, president of the board of education and president of the Hudson County National Bank, died at his home in Jersey City, November 28, from arteriosclerosis, aged 65

Elizabeth Catherine Keller, M D Woman's Medical College of Pennsylvania, Philadelphia, 1871, after her graduation a member of the faculty of her alma mater, from 1875 to 1877 senior physician at the New England Hospital for Women, Boston a member of the New England Medical Society and for several years a member of the Boston school board, died at her home in Jamaica Plain Boston, November 29, aged 75

John Ely Brackett, M D George Washington University, Washington D C, 1870, a member of the Medical Society of the District of Columbia, for many years professor of practice of medicine and later professor emeritus of the principles and practice of medicine in Howard University, died at his home in Washington, December 3, from cerebral hemorrhage, aged 65

Adelbert John Douglass, M D Long Island College Hospital Brooklyn, 1872, a member of the Medical Society of the State of New York, a member of the staff of Ilion Hospital and one of the oldest practitioners of Herkimer County sometime president of the village of Ilion and a member of the board of education, died at his home, November 19, from pneumonia aged 75

Edwin Fletcher Ward, M D College of Physicians and Surgeons, New York City 1861, a member of the Medical Society of the State of New York, surgeon of the Twenty Eighth Massachusetts Volunteer Infantry and later on the staff of General Sheridan during the Civil War, died at his home in New York City, November 23 from arteriosclerosis, aged 76

Edward John Kiepe, Jr, M D University of Buffalo, N Y 1897 a member of the American Medical Association, adjunct professor of materia medica and pharmacology in his alma mater, was found dead in a hotel in Kansas City, November 23 from the effects of poison believed to have been self administered with suicidal intent, aged 40

Lee Balfour Slauter, M D College of Physicians and Surgeons New York City, 1882, for thirty years a practitioner of Fort Worth Tex, died in his office, November 22, from the effects of a gunshot wound of the head, self inflicted, it is believed, with suicidal intent, while despondent on account of business worries aged 54

George Gerald Allred, M.D Medical College of Indiana, Indianapolis 1905 of Danville, Ind, a member of the American Medical Association coroner of Hendricks County from 1908 to 1912 died in the Methodist Episcopal Hospital Indianapolis, November 26, after an operation for appendicitis, aged 30

Charles H Philpott, M.D University of Iowa, Iowa City 1882 vice president and director of the Des Moines Life Insurance Company, died at his home in Des Moines, November 25, from nephritis, aged 52

Thomas A Boggan, M D Memphis Hospital Medical College, Memphis, Tenn, 1896, of Tupelo, Miss, a member of the Mississippi State Medical Association, health officer of Lee County and for several terms a member of the legislature, died while making an address in a school at Mooresville, November 20, aged 65

George Ebenezer Francis, M D Harvard Medical School, 1863, a member of the Massachusetts Medical Society, assistant surgeon in the Navy throughout the Civil War, consulting physician to the Worcester City and St Vincent's hospitals, died at his home in Worcester, November 20, aged 74

John T Hawkins, M.D University of Louisville, Ky, 1881, a member of the Arkansas Medical Society, of Mount Holly, aged 57, was thrown from his horse while making a professional call near Mount Holly, November 20, and, his foot catching in the stirrup, was dragged to death

Abraham Lincoln Fox, M D Rush Medical College, 1882 of Danville, Ill, a member of the American Medical Association, died in St Elizabeth's Hospital, Danville, November 28, from acute nephritis, for which an operation had been performed two days previously, aged 54

John E Bruere, M D Washington University, St Louis, 1858, surgeon of United States Volunteers during the Civil War, formerly a practitioner of St Charles Mo, but for the last five years a resident of New York City, died at his home, November 22, aged 75

Thomas Mifflin Butler, M.D Eclectic Medical Institute, Cincinnati, 1857, formerly a practitioner of Pecatonica, Ill, for twelve years circuit clerk and recorder of Winnebago County, died at his home in Rockford, November 28, from cerebral hemorrhage, aged 79

Lewis Nelson Davis, M D Miami Medical College, Cincinnati, 1873, of Farmland, Ind, a member of the American Medical Association, president of the Farmland State Bank, died in Harper Hospital, Detroit, Mich, October 3, after a surgical operation, aged 63

Alvin Matthew Cushing, M.D Homeopathic Medical College of Pennsylvania, Philadelphia, 1856 formerly a member of the staff of the Wesson Memorial Hospital, Springfield, Mass, died at his home in that city, December 1, from cerebral hemorrhage, aged 83

Angus MacOdrum, M D Jefferson Medical College, 1900, a member of the American Medical Association, for many years connected with the Cambridge (Mass) Relief Hospital, died at his home in Cambridge, November 23, from cerebral hemorrhage, aged 47

Philip McNab, M.D Long Island College Hospital, Brooklyn, N Y, 1863, contract surgeon U S Army during the Civil War, an expert in medicolegal chemistry, died at his country home near Mooresville, Ind, about November 29, from pneumonia, aged 79

William H Jenney, M.D Cleveland Homeopathic Medical College, 1862 a member of the hospital corps of the Army during the Civil War, first secretary of the Missouri State Homeopathic Medical Society, died in San Diego, Cal, October 19, aged 72

Asbury J Russell, M D University of Wooster, Cleveland, O, 1868, medical officer of volunteers during the Civil War, of Oakland Cal, formerly a trustee of Merritt Hospital, died in Grass Valley, Cal, November 26, from cerebral hemorrhage, aged 67

Edward Wright Smitheman, M D University of Pennsylvania, Philadelphia, 1898, of Oil City, Pa, a member of the American Medical Association, died at the home of his parents, in Philadelphia, November 27, from tuberculosis, aged 37

William D Stumbaugh, M D Baltimore University, 1897, of Lacona, Ia, died in that place, November 21, from the effects of a gunshot wound of the head, self inflicted, it is believed, with suicidal intent, while mentally deranged, aged 53

Harry Milton Ferguson, M D Rush Medical College, 1890, of Morris, Ill, a member of the American Medical Association and secretary of the Grundy County (Ill) Medical Society, died November 19, from rheumatism, aged 43

Maurice Francis Sullivan, M.D Dartmouth Medical School, Hanover, N H 1886, for many years a practitioner of Southington, Conn, died at his home in Brooklyn, N Y, November 29, from cirrhosis of the liver, aged 48

D L Benson, M.D St Louis Eclectic Medical College, 1883, died suddenly in a store near his home in Mountain Grove Mo, November 23

John F. Cherrington, M.D. Marion Sims College of Medicine, St. Louis, 1895; died at his home in Denver, November 27, from the effects of poison, believed to have been self-administered with suicidal intent, aged 48.

H. J. Salley, M.D. Medical College of Georgia, Augusta, 1885; formerly president of the Bank of Salley, S. C., and a member of the board of education; died at his home, November 22, from cerebral hemorrhage, aged 52.

William Campbell (license, years of practice, Illinois, 1878), for many years a practitioner of Equality, Ill.; died at the home of his son in Danville, Ill., November 20, from accidental strangulation, aged 70.

Carlisle Milton Southard, M.D. Ohio Medical University, Columbus, 1902; a member of the Ohio State Medical Association; died at his home in Zanesville, O., November 21, from heart disease, aged 37.

Eliphalet Comer Baldwin, M.D. University of Colorado, Boulder, 1897; a member of the legislature from Custer County in 1910 and 1911; died suddenly at his home in Westcliffe, November 26, aged 36.

Walter Henry Tobey, M.D. New York Homeopathic Medical College, New York City, 1874; died suddenly in his automobile in front of his home in Boston, November 23, from heart disease, aged 65.

Merchant Charles Fargo, M.D. Rush Medical College, Chicago, 1912; intern in the House of Correction Hospital; died November 26, from shock, two days after an operation for hernia, aged 27.

Richard J. Brady, M.D. Jefferson Medical College, 1909; of Hastings, Minn.; deputy coroner of Dakota County; died in St. Johns Hospital, St. Paul, November 26, from pneumonia, aged 28.

Henry Diers, M.D. St. Louis College of Physicians and Surgeons, 1882; for twenty-five years a practitioner of Kansas City, Mo.; died at his home, November 28, aged 78.

Ernest Duval, M.D. Laval University, Quebec, 1884; formerly a member of the city council and school board of Rochester, N. H.; died at his home, November 23, aged 52.

Charles W. Hume, M.D. Detroit (Mich.) Medical College, 1876; of Corunna, Mich.; died in the Petoskey (Mich.) Hospital, November 22, from heart disease, aged 63.

Alexander W. Gray, M.D. University of Tennessee, Nashville, 1890; for fifteen years a practitioner of Pauls Valley, Okla.; died at his home, November 15, aged 58.

Eva Viola Mead, M.D. University of Buffalo, N. Y., 1900; a member of the Medical Society of the State of New York; died at her home in Buffalo, November 20, aged 41.

Celestia D. Messinger, M.D. Bennett Medical College, Chicago, 1883; for many years a practitioner of Chicago; died at her home in Brooklyn, December 5, aged 70.

Nathan G. Reiff, M.D. Hahnemann Medical College, Philadelphia, 1883; died at his home in Albion, Ind., November 26, from acute disease of the throat, aged 53.

Alice Bunker Stockham, M.D. Chicago Homeopathic Medical College, 1882; formerly of Chicago; died at her home in Alhambra, Cal., December 2, aged 79.

John W. Barry, M.D. Eclectic Medical Institute, Cincinnati, 1905; formerly of Springfield, O.; died at his home in Cincinnati, November 25, aged 31.

Jesse Bertram Wiley, M.D. College of Physicians and Surgeons, Chicago, 1902; of Osmond, Neb.; died suddenly at Pierce, Neb., November 4.

Samuel McCloskey Cleveland, M.D. Hahnemann Medical College, Philadelphia, 1875; died at his home in Philadelphia, November 23, aged 75.

Dennis Jerome Sullivan, M.D. Bellevue Hospital Medical College, 1876; died suddenly at his home in Providence, R. I., October 20, aged 62.

Griffin T. Dailey, M.D. College of Physicians and Surgeons, Baltimore, 1884; died suddenly at his home near Romney, W. Va., November 22.

Russ R. Roberts (license, Arkansas, 1903), of Brookland, Ark.; died in Nettleton, Ark., November 18, from typhoid fever, aged 38.

Francis Findlay, M.D. University of Buffalo, N. Y., 1860; of Franklinville, N. Y.; died in Parkville, Mo., October 3, aged 78.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

BAUME ANALGÉSIQUE BENGUÉ

A physician writes asking for the formula of Baume Analgésique Bengué. This product is another of the "patent medicine" 'ethical proprietary" type of nostrums. In Great Britain, it is advertised to the public as "A Wonderful Remedy for Rheumatism, Gout, Neuralgia." In this country, the exploiters find that space in cheap medical journals, reinforced by the aid of undiscriminating physicians, is a cheaper method of getting the stuff to the public. According to the statements of the manufacturers, Bengué's Analgesic Balm contains "menthol, salicylate of methyl and lanolin." When analyzed by the chemists of the British Medical Association, it was reported to have the following composition:

Menthol	18 per cent.
Methyl salicylate	20 per cent.
Lanolin anhydrous	54 per cent.
A fat apparently lard	8 per cent.

The estimated cost of the ingredients of a 50-cent tube of Bengué's Analgesic Balm, according to the British chemists, is 2½ cents. Evidently this imposingly named product is practically a lanolin ointment containing oil of wintergreen and menthol. Similar products are catalogued by various pharmaceutical houses under various names and with varying degrees of frankness concerning their composition. Two firms give the medical profession full details regarding the composition of their products. The H. K. Mulford Company who sell it under the name "Methyl Salicylate Ointment," and the Pitman-Myers Co. who name their product 'Anodyne Balm, P. M. Co." Some other firms are not so frank. Parke, Davis & Co., for instance, sell "a combination of methyl salicylate and menthol with a lanolin base" under the name 'Analgesic Balm," but do not give the quantities of the ingredients. Frederick Stearns & Co. sell "Analgesic Cream, Stearns" without giving the quantities. Nelson Baker & Co. sell "Anti-Neuralgic Ointment," and no quantities are given.

THE EVOLUTION OF A PROPRIETARY—LYSOL

Regarding certain proprietary preparations and their equivalents found in pharmacopeias or other standard works of reference, it is often questioned whether the proprietary is the original and the official preparation, the imitation or vice versa. As a general proposition, medicinal compounds and preparations are not born but evolved, as in the case of epinephrin, in which the credit of discovery belongs to no one person, but to several.[1] So it is often the case that the proprietary and official preparations may be based one on the other, while both are usually based on some preparation which antedates them. This is well illustrated by the proprietary preparation Lysol, the practical equivalent of which—liquor cresolis compositus—is official in the United States Pharmacopeia. After the discovery of phenol (carbolic acid) and the recognition of its germicidal value, it was gradually learned that other phenolic compounds occurring in the crude distillates from tar and wood were more efficient and less poisonous than phenol (carbolic acid). When this was discovered, attempts of course were made to utilize these higher and more efficient phenols, which meant that their insolubility in water had to be overcome. In these attempts there were efforts to form new compounds as well as a search for simple solvents. While the first failed, because these compounds were less efficient than the phenol from which they were made, a simple solvent was found in soap. The first attempt to utilize the solvent power of soap gave creolin, a mixture of the so-called crude carbolic acid (really containing but little phenol and consisting largely of higher phenols along with inert hydrocarbons) with soap This was followed in 1884 by Schenkel's discovery that a portion of this "crude carbolic acid" could be made soluble in water by treatment with soap Schenkel was refused a patent on the ground that any soap manufacturer should be permitted to add phenol to his soap, but in 1889 a patent for a cresol soap solution was granted to Damann, who used cresol, a constituent of "crude carbolic acid" The preparation was put on the market and has since been widely advertised under the proprietary name "Lysol"[2] It is thus seen that Lysol is a good example of the way in which manufacturers appropriate the discoveries of others, develop them and turn them to proprietary use

---

[1] The Journal A. M. A., March 25, 1911, pp. 901-910.

The ill deserved patent protection for Lysol happily expired long ago and the product can now be made by any one In view of the non descriptive character of the name "Lysol" and the danger in using such names in connection with potent and poisonous remedies, this cresol soap solution has been admitted to pharmacopeias not under the original name "Lysol" but under descriptive names such as that in the United States Pharmacopeia—"liquor cresolis compositus"

JIREH DIABETIC FOOD

"Can you give me any information as to the reliability of the claims of the Jireh Diabetic Food Company? The company claims to have treated the starch in the food in some way so that it can be taken by diabetics without increasing urinary sugar, and as the products made by the company are quite palatable they are preferred to the ordinary gluten flour"

This inquiry was received from Dr E. P Evans, South Milwaukee, Wis The Jireh Diabetic Flour is one of those vicious and fraudulent products—of which there are many on the American market—that contain practically as much starch as ordinary flour but are sold under misleading names as safe products for diabetics The law that made lying illegal has produced many changes in the Jireh advertising To tabulate

BEFORE	AFTER
Jireh Diabetic Flour	'Jireh Flour
Jireh Diabetic Foods	Jireh Diatetic Foods
Jireh Starch *Changed* Foods	Jireh Starch *Treated* Foods
No chemicals are used in the *change* of the starch	No chemicals are used in the *treatment* of the starch

It is worth noticing that the Jireh concern has coined a word— diatetic"—and uses it throughout its advertising matter This word is used wherever the word "diabetic" formerly occurred in the Jireh circulars It is doubtless in line with the general attempt to deceive the public without actually violating the letter of the law The booklets sent out by the Jireh Company still contain a vast amount of pseudoscientific non sense although not so much now as they did a few years ago The claim made by the concern that the starch in their flour and foods is so changed as to be harmless for the diabetic is a cruel falsehood To quote from a report by Dr A. L Winton, Chief of the Chicago Laboratory of the Bureau of Chemistry, United States Department of Agriculture

> The Jireh Diabetic Food Company designate their foods as starch changed but our analyses and microscopic examinations do not indicate that the change if any is of a kind that renders the materials less objectionable for diabetic use

As a matter of fact Jireh flour contains practically as much starch as ordinary wheat flour To be exact Jireh flour contains 73 02 per cent carbohydrates while ordinary wheat flour contains about 75 per cent Ordinary flour sells at the rate of about $3 a hundred pounds Jireh flour sells for $11 a hundred pounds These products were discussed in The Journal, Sept 12 1908 p 932 and Nov 21 1908 p 1799

---

Cesarean Section from the Point of View of a Patient

To the Editor—Early last fall when it became positive that I was pregnant and not suffering from the menopause or a pseudocyesis I had to consider seriously the outcome to myself and to the child

The thought of a long tedious labor with extensive perineal repair and, if forceps became necessary, the probable death of the much wanted little one was not pleasant to contemplate and led me early to look up carefully the subject of cesarean section, which I selected for the following reasons age 41, first pregnancy, measurements small, the probability in an elderly primipara of the baby being a boy with a large head like his father, the better chance for a living baby, the elimination of perineal tears with the resulting invalidism, and finally the small mortality to both mother and child when the operation is undertaken just before labor begins

Having settled the matter of cesarean section definitely in my own mind I found a surgeon who coincided with my views, especially when the later examinations showed a malposition of the child This decision made for peace of mind, as much as did the continuing of my active work during the entire time of carrying the baby

On the morning of June 13, 1912, having had mild uterine contractions most of the previous night, I went to the hospital after a breakfast of shredded wheat, milk and soft boiled egg reaching there about 10 a m I was immediately prepared in the usual way for a major operation, going within the hour to the operating room, thus avoiding the long dreary wait through which a patient usually passes when entering the hospital the night before At my own request I was allowed to have the anesthetic on the operating table rather than in the anesthetic room, so as to lessen the possibilities of asphyxiating the baby I counted only five breaths before I lost consciousness and knew nothing more until I reacted in my room at 2 30 p m My chart says that I had severe uterine contractions, which are vouched for also by my husband, but my only remembrance of this time was an inordinate thirst and my insistence on having a continuous supply of cracked ice, which was granted, and the three hypodermics of morphin and atropin, which were given me during the first night. Several days later desiring to cough I suddenly discovered the soreness of my abdomen and the presence of the incision I had no nausea whatever until given an enema the night of the second day and again on the fourth day following a dose of Rochelle salts I did suffer intensely from gas in the intestine but this was relieved, as a rule, by the passage of a rectal tube At the end of the first week I was annoyed by drenching perspiration at night In ten days the stitches, in three continuous sutures, were removed At the end of two weeks I was out of bed, in eighteen days I was home and I went down stairs on the twenty third day At no time did the temperature go above 100 F and to that only on two days during the first week With plenty of ice and orange albumin water I fared nicely until soft diet was allowed on the third day, which was followed shortly by regular diet

The child instead of being a large headed boy was a moderately small girl weighing 6¼ pounds, and is at present doing well My friends remarked on the nice appearance of the baby which no doubt was due to the lack of compression The presence in the uterus of a number of fibroids probably caused the malposition of the child

In closing I wish to express my appreciation of Dr M Louise Strobel and Dr Albert Stavely for my exceptionally good condition at present and for permission to present this case

Martha M. Brewer Lyon, M D, Washington, D C

State Supervision of the Feeble Minded

To the Editor—I believe that you have well summed up the situation in the last sentence in your editorial on "The Elimination of Feeble Minded Strains" (Nov 16, 1912, p

801) "Considered in all its various aspects it would appear that the most practical plan for the elimination of the feeble minded strains should judiciously combine the methods of segregation and sterilization.'

That there may be, however, such "judicious combination of segregation and sterilization" there must first be a census of all the feeble minded in the state The state committee on lunacy of each state should know exactly the names and location of all feeble minded persons in the state, and should be charged with authority to compel any feeble minded person to enter an institution whenever it deems that such action is for the public welfare, it should likewise have authority to detain a feeble minded person in such an institution In short, the state should have supervision over all the feeble minded within its borders whether in institutions or living outside, and should decide which may live outside institutions and which must live inside institutions At present this tremendously important question is largely decided by the parents and guardians of the feeble minded—the very persons who are least fitted to give judgment on these questions They naturally consider not the welfare of the state but that of the individual

I believe such state supervision for the feeble minded is most fundamental. When this has been established I would say with you, that "the most practical plan for the elimination of the feeble minded strains should judiciously combine the methods of segregation and sterilization" But first of all the state must assume full authority over all feeble minded within its borders

Theodore Diller, M.D, Pittsburgh

BRUSSELS CONFERENCE AND TREATY ON UNIFORMITY OF POTENT DRUGS IN THE PHARMACOPEIAS

To the Editor —In the review of the 'Digest of Comments on the Pharmacopeia of the United States of America Oct. 12 1912 p 1300 there appears reference to the treaty signed at Brussels and to a conference protocol Please explain what is meant by the Brussels conference and the protocol and treaty

Physician and Pharmacist

Answer.—In response to an invitation sent out by the Belgian government, at the request of the International Pharmaceutical Congress in Paris in 1900, delegates appointed by their respective governments met in Brussels in September, 1902 to consider the practicability of eliminating differences in the strength of certain potent medicaments bearing the same name in different pharmacopeias The conference agreed on a protocol in the form of three articles The first article included suggestions for uniform requirements for three chemical substances, nine drugs and thirty pharmaceutical preparations The second article proposed three general principles to be observed in compiling the several national pharmacopeias The third article suggested the expediency of adopting a normal drop counter for measuring out drop doses of potent liquid medicines The protocol was signed by the delegates at the conference, and, after submission to the home governments, by their diplomatic representatives

The treaty referred to was signed at Brussels, Nov 29, 1906, by the diplomatic representatives of the following governments Great Britain, Germany, Austria and Hungary, Belgium Bulgaria, Denmark, Spain, France, Greece, Italy, the Grand Duchy of Luxemburg, Norway, the Netherlands, Portugal, Russia, Servia, Sweden, Switzerland and the United States It is an agreement between the United States and the other governments respecting the unification of the formulas for potent drugs on the basis indicated in the protocol agreed on at the conference held in Brussels in September, 1902 This treaty represents the first practical step in an agitation continued for more than half a century, to bring about uniformity in the composition and strength of widely used medicaments The efforts made previous to 1900 were directed to the development of an international pharmacopeia and were futile because they were too comprehensive As an illustration of the practical results so far achieved it may be pointed out that, with the single exception of Great Britain, all the powers subscribing to the protocol of the Brussels Conference have now issued revised pharmacopeias and the total number of compliances with the requirements of Article 1 of the protocol has been increased from 129 in 1902 to 260 in 1910, while the points of non compliance have been reduced from 131 in 1902 to fifteen in 1910, the present United States Pharmacopeia being responsible for no less than five of the latter

Two important instances of the effects of this conference and treaty in securing uniformity in pharmacopeial preparations are the following dilute hydrocyanic acid, which before the conference varied in strength in the different pharmacopeias from 1 to 10 per cent of the acid (HCN) is now required to contain 2 per cent syrup of ferrous iodid, which formerly varied from 0.5 to 12 2 per cent of the salt (FeI_2), is now required to contain 5 per cent

DIAGNOSIS IN SUDDEN DEATH OF A CHILD

To the Editor —A female child, aged 19 months was suddenly taken ill at 7 in the morning and died in three hours She had been well and in good health before and was not noticeably ill during the night When called I found the child pale and limp with an apparent paralysis of throat muscles as she could with difficulty make a sound—saying once or twice mam There was considerable mucus blocking the upper air passages. Respiration was irregular and slow but not jerky temperature by axilla 98 There was no contraction of any muscles but relaxation was present Pupils were wide The child had not vomited or coughed There was no cyanosis Pulse was irregular and about 90 varying greatly, becoming much slower as the condition grew worse The child died in thirty minutes after my arrival Paralysis of respiration first appeared I maintained the respiration artificially for several minutes during which the pupils contracted and the child made a feeble effort at respiration The pupils soon dilated again and the heart ceased beating

I could obtain no history as to possible poisoning from without. The child at its supper had eaten a small amount of fresh sausage This was from their own hogs which they had just butchered under favorable conditions of weather (There was no diarrhea or distention) Father and mother and three other living children were healthy Family history was negative except that a year or two ago they lost a 4 year-old girl who they inform me, died after three or four hours illness and with precisely the same symptoms Can you diagnose the case or suggest a possible diagnosis?

George W Shriver M D Metz W Va

Answer —Without a necropsy it would be impossible to form a definite opinion with reference to the cause of death in this case Three principal causes should be considered botulism, infantile paralysis and lymphatism

1 Botulism is suggested by the history of eating sausage The symptoms of botulism are similar to those described, although usually not so acute As the sausage is stated to have been fresh, the probability of sausage poisoning is diminished but cannot be entirely excluded

2 Infantile paralysis sometimes produces death very rapidly, with paralysis of the throat muscles and of the respiration The absence of all indications of infection makes this cause very doubtful.

3 Lymphatism is a term given to a condition in which the thymus gland is much enlarged and the individual possesses only slight resistance to causes of death, so that sudden death may occur after slight causes, such as slight operation and mild infection, or even when no cause can be assigned. The symptoms in such cases are various and this condition may have been operative in the case described

A CASE FOR DIAGNOSIS PROBABLY SMALL-POX

To the Editor —Please diagnose the following case A boy aged 2 was taken suddenly ill with a temperature of 104 to 104 5 pulse 120 to 140 and respiration 35 to 40 He was delirious showed cerebral symptoms and rolled his head from side to side The temperature remained high and the pulse was frequent till the fourth day when an eruption similar to that of small pox or chicken pox appeared on the face and wrists but on no other part of the body Temperature fell but rose again in a few days and ranged from 99 to 101 5 The nose bled a little and seemed to be stopped up with something as from a bad cold On about the tenth day the nose discharged sanious pus There was never any membrane in the throat nor any history of exposure either to diphtheria or to small pox The mother who nursed the child was vaccinated early in the child s illness and on the twenty first day of the child s illness developed diphtheria

Could patient have had both small pox and diphtheria? If only diphtheria account for the eruption, which was identical with small pox except that it was scanty

W E Whiteside, M D Flatwoods W Va

Answer —From the history given by our correspondent we should think it probable that the case was one of small pox with a limited eruption The discharge from the nose was in all probability due to small pox vesicles on the mucous mem brane inasmuch as most small pox patients suffer from this symptom It is, of course, possible that small pox might be complicated by diphtheria, but we think that no such case is on record Only a bacteriologic examination could determine this point While the diagnosis of diphtheria in the mother's case may be correct, it is to be remembered that a membrane does not justify the diagnosis of diphtheria unless a microscopic examination has been made Membranes in the throat may be produced by a number of organisms, including the *streptococcus*, *pneumococcus*, the *organisms of Vincent's* angina and others A diagnosis of diphtheria should be based, whenever possible, on a bacteriologic examination of the secretions from the case

DIFFERENCE BETWEEN SALVARSAN AND NEOSALVARSAN

To the Editor —Why is neosalvarsan recommended not to be given subcutaneously though it can be given intramuscularly? What are the clinical differences between salvarsan and neosalvarsan given subcutaneously? Are their physiologic actions the same?

Joseph A Thomas, M D, Valdosta Ga

Answer —The manufacturers of neosalvarsan warn against the subcutaneous use of the remedy on account of the danger of producing infiltrations Aside from this, there seems to be no difference between the pharmacologic action of salvarsan and neosalvarsan Neosalvarsan is much less irritating to tissue than salvarsan The recommendation not to use it subcutaneously is due to the fact that any irritant drug is much more likely to cause sloughing when introduced subcutaneously than when put into the muscle Absorption is also quicker from the muscle

NOSTRUMS AND NEPHRITIS

To the Editor —I have under my care a patient with chronic parenchymatous nephritis Microscopic examination shows occasional epithelial casts with hyaline and granular casts The patient feels well and appears to enjoy the best of health Please give me your opinion on the use in such a case of the lymph injections put out by the Animal Therapy Company of Chicago, from whom I have just received a supply of literature

S T D

Answer —The *Council on Pharmacy and Chemistry took* up for consideration the "Lymph Compound R H," and "Orchitic Fluid Tablets," sold by the Animal Therapy Company and refused them recognition

The treatment of a case of chronic parenchymatous nephritis is a task requiring the best judgment and the greatest knowledge that the physician can command From the first his aim should be to do no harm, and with this in view he will recognize that since we do not know the cause of this disease, and since we are unable to influence the essential process in the kidney, the administration of a remedy capable of doing harm should be undertaken only under the clearest indications It is probable that the remedy proposed, containing, it is asserted, a mixture of foreign proteins might injure healthy kidneys, to say nothing of sick ones It is well known that foreign proteins such as the white of egg, if they enter the circulation unchanged, are excreted by the kidney and are liable to produce serious irritation, which in the case of parenchymatous nephritis might easily aggravate the existing condition and frustrate all other efforts at a cure More especially is it *imperative to do no harm* when, as in the case reported by our correspondent the patient appears to be in good health Two questions should be raised in that case First, is there any evidence that the occasional excretion of a few casts, whatever may be their variety is actually doing the patient any harm? And second, since there are no symptoms what possible improvement could be expected from treatment? It is admitted that we have no remedy which can effect an essential change in the condition of the diseased kidney What must be done in such a case is to spare the kidney—to require of it the minimum of functional activity In such a case the physician who introduces an animal protein, foreign to the human system, would be taking a serious responsibility The chances are that it would do harm how great, no one can tell If the physician can really make up his mind to experiment at the risk of the life of his patient this case appears to be one unusually favorable to the manufacturer of the serum. There are chances that the diagnosis may be incorrect and that such a condition of the urine does not indicate a serious condition of the kidney It is frequently the case after an acute infection, or some similar irritation, that the kidney continues for some time to excrete albumin and casts but the condition eventually clears up In such a case if the serum did no harm it would be given the credit of curing the patient who recovers in spite of it It is a little unfortunate, however, for the purpose of such demonstration that the patient is said to feel well If only he could be persuaded that he has a serious disease so that he might be somewhat depressed mentally, the effect of the cure would be more remarkable!

If the physician to whom such a patient comes for advice, instead of taking the wise course of seeking reliable information, were to take at their face value the statements of interested commercial manufacturers—if he were to administer this unknown and dangerous remedy, the effects of which he cannot *predict*—he *would commit a breach of trust* more culpable than the most vicious attempts of the nostrum maker to mislead the physician and the public

LITERATURE ON MALARIA

To the Editor —We are doing the postgraduate course and are beginning on the third month of the second year—diseases due to animal parasites Can you furnish me with or refer me to a library where I can get the most recent articles on malaria?

ANTIFREEZING MIXTURES FOR AUTOMOBILES

To the Editor —What chemicals or mixtures are best suited for preventing freezing in the water reservoir of an acetylene generator and in what proportion should it be added to the water to prevent freezing at 0 C (32 F) or —5 C (23 F)? Are alcohol and glycerin permissible? What is safe and non interferent with the action of water on calcium carbid? An answer to the above will also be of service to those who desire to prevent the freezing of the radiators of standing automobiles

Edmund P Fowler New York

Answer —As our correspondent says, information on this subject is not plentiful In the following answer we quote rather freely from an answer to a similar query contained in the *Bulletin of Pharmacy* and from Meyer Brothers' *Druggist*, both of November, 1911 What follows refers more particularly to the prevention of freezing in automobile radiators, fire extinguishers, etc In the selection of a non freezing solution for an automobile the action of the solution on the circulating system and also the capacity of the solution to withstand high and low temperatures are the points to be considered Among the solutions used for this purpose are sodium chlorid and calcium chlorid solutions glycerin, wood alcohol and denatured alcohol When salt solutions such as calcium chlorid, sodium chlorid, etc., are used, two corrosive actions, chemical and electrolytic, take place Calcium chlorid is apt to contain hydrochlorid acid which if not neutralized will attack metals, and directions are usually given when this is used to neutralize by the addition of an alkali Caustic solutions, however, are just as destructive as acid solutions, forming hydrates on the different metals composing the circulating system This chemical action, though serious, is probably second to the electrolysis which occurs universally when salt solutions are employed, and causes a rapid eating away of the metals Sodium and calcium chlorid solutions in the strength of 0 5 pound per gallon freeze at 24 and 29 F, respectively, and in the strength of 3 5 per gallon freeze at —8 F

Glycerin makes a pretty good antifreezing mixture as it boils at an extremely high temperature and its freezing point can be reached only by artificial means In addition to its cost however, which is considerable, it has some objections Unless chemically pure, it is apt to contain fatty acid, and it produces destructive chemical action It also destroys rubber connections and after a short time becomes foul and requires frequent renewal Glycerin has been recommended for use in fire extinguishers, an addition of 3½ quarts to a standard extinguisher making a solution capable of withstanding —4 F, and 4 quarts a temperature of —10 F This use would be similar to that in the acetylene generator and though a mixture of glycerin and water would probably not prevent the generation of gas, a considerable quantity of glycerin mixed with the water might retard it We have no evidence on this point

Wood alcohol and denatured alcohol are good agents for this purpose Wood alcohol has been stated to have a slight tendency to produce formic acid which would in time corrode the metal parts It also boils at a lower temperature than denatured alcohol and less of the latter is required, as the tendency to evaporate is less Denatured alcohol is also much cheaper Denatured alcohol has no corrosive action on any of the metals, and its ability to withstand cold is indicated by the fact that it freezes at about —160 F It is manufactured by fixed formulas prescribed by the government and is therefore practically uniform It contains no solid matter and does not require filtration The freezing points of various mixtures of denatured alcohol with water are about as follows

20 per cent solution	10 F
30 per cent solution	—5 F
40 per cent solution	—20 F
50 per cent freezes at about	—35 F

A mixture of denatured alcohol and water of sufficient strength to prevent freezing at anything but extraordinarily low temperatures probably will not very materially retard the action of the water in generating acetylene gas from the carbid

It will appear from the above that denatured alcohol is probably the most satisfactory and cheapest medium for preventing freezing in automobile radiators, fire extinguishers and gas generators

Reorganization of the Medical Department of the University of California

At a meeting of the regents of the University of California in December, 1911, the committee on Medical Instruction recommended that the departments of the medical school in Berkeley and San Francisco be brought together in San Francisco as soon as possible, that the clinical years be put on an academic basis and that a proper teaching hospital and proper laboratories be provided It was declared to be the regents' desire to establish a medical school of the highest standard

Official information is received that at a meeting in April 1912, on the recommendation of the medical faculty, the following plan of reorganization was adopted

Clinical instruction in the medical school is to be carried on in three main departments

1 Gynecology and Obstetrics It was decided to put this department on an academic basis at once and to allot full academic salaries for a professor and an assistant

2 Medicine This department to include pediatrics, neurology and dermatology This department cannot as yet be placed on a full academic basis, but the payment of assistants for the current year has been provided for

3 Surgery This department to include orthopedics, urology, ophthalmology, rhinology, otology and laryngology As with medicine, there were not sufficient funds available this year to put the department on a full academic basis, but three paid assistants have been provided for

In addition to the main departments, the work of the hospital pathologist was reorganized and an additional assistant professor of pathology was secured

In accordance with the plans adopted by the regents, a *movement is on foot to provide a new university hospital* The present plans aim at four units of forty or fifty beds each to be devoted respectively to surgery, medicine, diseases of women and diseases of children Money has already been given ($350 000) by private persons to build and equip the departments of medicine and children s diseases In order to carry on the work in the present buildings the regents have granted $20,000 for alterations in the hospital for accommodation of clinics and for equipment of clinical and pathologic laboratories. A children's ward has been added in the hospital

New Hospital Dedicated

The new teaching hospital of Meharry Medical College, the George W. Hubbard Hospital, was dedicated Nov. 29, 1912. Addresses were given by a number of prominent men who are interested in the advancement of negro education. The total cost of the building was about $40,000. It is a brick structure three stories in height including the basement and comfortably provides accommodations for seventy five patients, or 100 patients in case of emergency. It was named in honor of the venerable dean of the Meharry Medical College.

Nevada November Report

Dr. S. L. Lee, secretary of the Nevada State Board of Medical Examiners, reports the written examination held at Carson City, Nov. 4-6, 1912. The number of subjects examined in was 13, total number of questions asked, 100, percentage required to pass, 75. The total number of candidates examined was 4, of whom 3 passed and 1 failed. Eight candidates were licensed through reciprocity. The following colleges were represented:

PASSED

College	Year Grad	Per Cent
Jefferson Medical College	(1910)	89.5
Laval University, Quebec	(1901)	78.3
College of Physicians of Ireland	(1885)	93.2

FAILED

College	Year Grad	Per Cent
Ohio Medical University	(1904)	63.3

LICENSED THROUGH RECIPROCITY

College	Year Grad	Reciprocity with
Hahnemann Med. College and Hospital, Chicago	(1890)	Illinois
Jenner Medical College	(1903)	Illinois
Hospital College of Medicine, Louisville	(1905)	Kentucky
Medical School of Maine	(1896)	Maine
Baltimore Medical College	(1908)	Maine
Univ. of Minnesota, College of Med. and Surg.	(1911)	Minnesota
St. Louis College of Physicians and Surgeons	(1895)	Iowa
Jefferson Medical College	(1898)	Penna.

Medical Economics

This Department Embodies the Subjects of Postgraduate Work, Contract Practice, Legislation, Medical Defense, and Other Medicolegal and Economic Questions of Interest to Physicians

THE OUTLOOK ON A NATIONAL DEPARTMENT OF HEALTH

The most promising feature of the campaign for national health organization is the growing understanding of the problem on the part of influential men outside of the medical profession. THE JOURNAL has repeatedly pointed out that a national department of health would have and could have nothing to do with the individual practice of medicine, that it could have no relation to "schools" of medicine, that it could not affect the individual rights of any one, and that its functions would be almost entirely educational and simply an expansion and coordination of the work already being done by existing bureaus and divisions now scattered in different parts of the executive department. Evidently the truth of these facts is being realized by all except those who are too ignorant or too prejudiced by partisan bias to appreciate the facts, or by those who are too much influenced by selfish considerations to desire the passage of the measure for the public good. In last week's issue of the *Outlook* appears a splendid editorial on this subject. It presents such a calm, accurate and well considered discussion of the subject as to justify reprinting the greater part of it. After discussing the difference between our private and our public interest in health matters the *Outlook* says:

"There is no question of the right of the federal government to conduct such a department. It has as much right, for example, to put up barriers against disease as it has to put up barriers against goods of foreign manufacture. Moreover, it is exercising its right already through various disconnected agencies, such as the Public Health Service and the officials who are engaged in the enforcement of the pure food law. The question is not whether the federal government shall exercise the right or not, but whether it shall exercise that right intelligently and effectively by means of a single, unified, administrative body devoted solely to matters of health.

"Suppose such a department were established, what would its functions be?

"In the first place, there should be no misapprehension as to what those functions would not be. The federal Department of Health would not be concerned with the treatment of individual cases of illness. It would not have anything to do with the 'healing art.' The officers of such a department would not be engaged in making sick people well.

"Unfortunately, some of the advocates of such a department or service have done much to create a wrong impression on this point. For example, the national platform of the Progressive party, in its plank favoring the 'union of all the existing agencies of the federal government dealing with the public health into a single national health service,' adds the phrase 'without discrimination against or for any one set of therapeutic methods, school of medicine, or school of healing.' The platform might as well have opposed discrimination against or for any school of theology. With the work of such a Department of Health, so called therapeutic methods, schools of medicine, or schools of healing, have nothing whatever to do. One might as well say that in establishing the Bureau of Chemistry there should be no discrimination against or for the practice of alchemy, or in the work of the Geodetic Survey there should be no discrimination for or against astrology. The Bureau of Chemistry is concerned only in ascertaining and acting on the facts of the science of chemistry. The Geodetic Survey has only to take into account the scientific work of geographers, mathematicians, and astronomers. And so the sole basis of such a Department of Health as is proposed should be, and must necessarily be, the facts of science as ascertained by the scientific methods of the laboratory. As a matter of fact, there is no confusion regarding this. It must be remembered that there is nothing essentially new so far as the nature of the work itself is concerned. It should not be forgotten that it was the United States government which carried on the investigations that resulted in the expulsion of yellow fever from the Canal Zone. The federal government did not engage in curing people, except in so far as it employed physicians to care for those for whom it was directly responsible, as it employs physicians and surgeons in the Army and Navy. So far as the public is concerned, its work had nothing whatever to do with methods of therapeutics or schools of healing. It was a scientific work as firmly based on the facts of science as the engineering work in the construction of the canal and its locks. It was an error to introduce the question of schools of healing into the proposal for a unified public health service or department, and it should not be repeated. The one form of discrimination which such a department should practice should be against the unscientific, and for the methods of the ascertained facts of science.

"The primary function of such a Department of Health is that of acquiring and distributing information. In other words it should do for the health of the people what the Department of Agriculture is doing for the agriculture of the people. The officials in the Department of Agriculture have at no time attempted to tell farmers how they must plow their land or sow their seed. The Department of Agriculture is continually studying the question of soil, of seed, of animal life, and of agricultural methods, and is storing up and tabulating this information. And then it makes this information accessible to those to whom it will be useful, it answers the queries of farmers, it sends out its instructors. This is just what such a Department of Health would chiefly do with regard to the health of the people. At present there are no uniform vital statistics for the United States. There is no means, for example, of accurately ascertaining what the death rate in America is.

"Secondarily, its function would be regulative. Now the United States government does to some extent establish health regulations. But only to some extent. To-day the nation at large must depend for protection against the invasion of cholera through the port of New York, not on its national servants, but on officials of the state of New York. It so happens that in the past the state of New York has done some exceedingly competent work in this respect, but the people of Ohio and of Pennsylvania and of Minnesota, and of other states where immigrants go, should not have to be dependent on the efficiency of the state government in New York to be adequately protected against the disease which may at any time become a menace to the whole nation by appearing at the port of New York. It is as much the function of the fed eral government to fortify the nation against foreign disease as it is to fortify the nation against foreign armies It cannot do so adequately until a single, united body for that purpose is established as its instrument

"The question whether such a body should be a Department with a Cabinet officer at its head, or a bureau erected in one of the departments, or an independent commission having no relation to any department, like the Interstate Commerce Commission, is not an unimportant question, but it is a secondary one It would be better, however, to have a bureau or an independent commission rather than not to have a unified body at all The prime duty of Congress in the protection of the health of the American people is to unite the various disconnected, and sometimes conflicting, agencies of the government into a single body and to give it power first to acquire the necessary information, second, to make that information accessible to the public, and, third, to enforce generally and effectively such regulations as are now enforced by the federal government sporadically "

A PLEA FOR A SQUARE DEAL FOR THE PATIENT

Practitioners, says R R White (*Texas State Journal of Medicine*, November, 1912), should not become so interested in each other as to deprive the patient of his square deal

"The daily press and popular monthly magazines are beginning the discussion of this fee splitting business The people have been kept in ignorance of the plan, or it could never have reached its present magnitude Organized medicine has been negligent Had the people been fully advised at the beginning of the practice they would themselves, as a matter of self protection, have stopped it They would have said to the family physician, 'I want to pay you for your services I want to pay you for your examination and for your advice If you have advised operation I want to pay you for that If you have advised me to take one of my loved ones to a hospital for operation, and in your conscientious judgment as my physician as the guardian of the health of my wife and children, as my friend and confidential adviser, you can add safety to my dear one by going with me to consult with the specialists we are going to employ to operate, then by all means go, give the specialist the benefit of your acquaintance with the family the benefit of your observation and treatment of the case and render me your bill for the service But, remember, doctor, you are working for me, you are the custodian of the health of my family, the question of life or death may depend on whether or not you have made a wise selection of the operator Do not allow yourself to be influenced by personal friendship for some particular specialist, do not allow yourself to be influenced by some personal grudge, and, by all manner of means, do not take my sick to one who will pay you a fee for the favor If the specialist is willing to pay you a fee for bringing him the patient, there is the beginning of a collusion between you, where, for financial reasons you will protect the specialist and he will protect you, and the Lord, unaided by that greatest boon to suffering humanity—a loyal, conscientious family physician—will have to care for my child alone Doctor, don't put yourself in a position to be unwisely unwittingly or selfishly influenced You are in my employ, I will compensate you as best I can, and I want to know that I have received that to which I am entitled—your whole soul, honest conscientious advice and, irrespective of results, I will know that my friend, my adviser, my doctor, has given the patient a square deal'"

White believes that whenever the people understand the question thoroughly it "will not be necessary for us to discuss it in medical meetings, for they will themselves condemn the practice of fee splitting and stop it As a matter of common sense, the people will know that their family physician cannot give them an unbiased opinion when he is being secretly paid for his advice by another, who is to profit thereby, and when they realize that such is the case, they will lose confidence in him and will employ a new family physician."

When the family physician takes his case to the specialist, White would have him say, "'Here is my patient here is the history, here is the result of my treatment, my observations and conclusions. Make your examination and give me your advice as to operation or treatment I have advised the family that my visit and consultation would be $25 (or maybe $100), that they should provide for that before paying you your fee, that my services were rendered first, and by priority should be paid first, that if they have not enough to pay us both they should give you a note for the balance due you'

"Would this be fair to the specialist? To be sure it would, and all whole souled men would approve it and, best of all, it would be fair to the patient, for it would insure him that to which he is entitled—a conscientious, frank, business like handling of his case Those specialists who are paying commissions for their cases have manufactured a smooth, plausible story to repeat to the general practitioner, and the burden of the song is square deal and 'live and let live,' but the square deal does not apply to the patient and the live and let live is not meant for him it is all for the doctor If it means anything in particular to the patient, it may mean that he has been bartered as a piece of merchandise"

The substance of the whole question is that the secret division of fees like secret rebates and commissions in the business world, is dishonest If it was not, there would be no reason for keeping it secret The general practitioner will be more sure of a square deal" if he insists on all transactions between the patient, the consultant and himself being known to all

Book Notices

Grundzuge der pathologisch histologischen Technik Von Dr Arthur Müllberger M R C S (England) L R C P (London) Paper Price 2 marks Pp 86 Berlin Julius Springer 1912

The object of this little pamphlet is to select laboratory methods that have been found most useful in practical work and disentangle them from the mass of procedure described in the large works on technic As a result we have in the space of a few pages clear directions for performing the usual tasks of pathologic histology that are required in ordinary clinical laboratories The choice of methods is for the most part good and the directions are plain and easily followed As the author recommends formaldehyd solution for almost everything, it would seem a wise precaution to warn his readers that constant use of this fixative often leads to serious dermatitis

Elementary Bacteriology and Protozoology The Microbiologic Causes of the Infectious Diseases By Herbert Fox M D., Director of the William Pepper Laboratory of Clinical Medicine in the University of Pennsylvania Cloth Price $1 75 net. Pp 237 with 72 illustrations Philadelphia Lea & Febiger 1912

In this little book the author has endeavored to answer the question as to how and under what circumstances bacteria produce disease. The book is elementary in its scope, suitable for nurses for instance, and beginners in general in the study of bacteriology There is very little discussion of any technical matters The book can be recommended as thoroughly reliable

Die Migräne Von Edward Flatau Monographien aus dem Gesamtgebiete der Neurologie und Psychiatrie. Herausgegeben von A Alzheimer und M Lewandowsky Part II Paper Price 12 marks Pp 253 Berlin Julius Springer 1912.

In this monograph the author has brought together the various disease pictures commonly called migraine and treated them under one heading He discusses the subject under (1) the vulgar or simple (2) the ophthalmic, (3) the epileptic (4) the psychic (5) the ophthalmoplegic, (6) the facioplegic varieties of migraine Though based on the literature of the world, the monograph is not mere compilation On the contrary, the author has views of his own for instance he does not hesitate to infer a relation between migraine and epilepsy Among the 500 cases of migraine which he had observed he found thirty six with epilepsy either as an equivalent or as a complication In the majority of his cases migraine occurred before the en developed and with its appearance the attacks of her became less frequent or entirely disappe states the more nearly symptoms app ore likelihood is there of epilepsy supervening His discussion of the rather unusual type of psychic migraine is full and interesting He found it present in a rudimentary form in about 26 per cent of all his cases, manifesting itself as a mild depression A patient of this type he pictures as an individual misanthropic and egocentric, who shuns society and narrows his mental horizon until he gradually becomes asocial, though still capable of performing his daily routine work In his discussion of the nature of the disease complex called migraine Flatau goes fully into the various theories advanced, but he himself leans to the view that the condition belongs to the family of metabolic disorders of which gout is a prominent member Under treatment, conformably to the latter view, he advises among other things a diet free from purins and publishes a list of articles for those affected with migraine in which meats, fish, coffee, tea and cocoa are practically excluded Of drugs he favors the lengthy administration of bromids, but omits to mention the routine prescription of a reliable preparation of cannabis indica in ascending doses, from which English and American neurologists have derived considerable success in a number of selected cases After following the author in his logical deductions with reference to etiology, pathology and diagnosis the sufferer from migraine will nevertheless seek in vain for something new to assuage his nerve racking pain The book on the whole is a meritorious one and deserves especial praise for its concise language and the absence of padding

The Nervous System An Elementary Handbook of the Anatomy and Physiology of the Nervous System For the Use of Students of Physiology and Neurology By James Dunlop Lickley M D Demonstrator of Anatomy University of Durham College of Medicine Cloth Price $1 80 net Pp 130 with 118 illustrations New York Longmans Green & Co 1912

This book owes its origin to the necessity that the student of modern psychology know the essential facts regarding the structure of the nervous system though he need not trouble himself about details As such facts are given in text books of anatomy in too great detail and it would be necessary for the student to purchase the entire work, the author has endeavored to state in plain language the principal features of nervous anatomy and physiology so that the non medical student can readily understand them The purpose has been well carried out and the treatise is interesting and profitable reading for the medical man as well as for the layman The author voices the hope that, while intended primarily for non medical readers, the book may prove acceptable to the medical student for preliminary study It might even be contended that the knowledge found in a simple text book like this is as much as the average medical man will retain and that such a work thoroughly mastered might help the physician to retain clearer ideas of the structure of the nervous system than he acquires from the laborious study of more detailed treatises

Dental State Board Questions and Answers By R Max Goepp M D Professor of Clinical Medicine at the Philadelphia Polyclinic Cloth Price $2 75 net Pp 428 Philadelphia W B Saunders Company 1912

This book is said to be based on questions collected from lists published during the last few years in the various dental journals The questions therefore, are representative of those asked by state dental boards It is asserted that questions which have been asked repeatedly and by the majority of dental examining boards have been included, followed in each instance with the answer given as briefly as was compatible with clearness The book will doubtless be of service to those who are preparing for an examination for a license to practice dentistry

The Imperial Cancer Research Fund Under the Direction of the Royal College of Physicians of London and the Royal College of Surgeons of England Fifth Scientific Report of the Investigations By Dr E F Bashford General Superintendent of Research Boards Price 5 shillings Pp 94 with Illustrations London Taylor & Francis 1912

This report is characterized by the same excellent publication and the numerous splendid illustrations of J R Ford, as the preceding reports have been, and gives substantial evidence of the vigor and fundamental sanity of the investigative work being conducted under the fund The articles here reported all deal with investigations on natural and acquired resistance of animals to experimentally induced cancer, under the following titles "The Manifestation of Active Resistance to the Growth of Implanted Cancer," B R G Russell, "A Cytologic Analysis of the Reaction in Animals Resistant to Implanted Carcinoma," C Da Fano, "The Nature of Immune Reaction to Transplanted Cancer in the Rat," W H Woglum, "Immunizing Power of the Placenta, Blood, Embryonic Skin, Mammary Gland, and Spleen of the Different Species Against Carcinoma of the Mouse," S Higuchi

Medicolegal

Statutory Privilege and Its Waiver

(Studebaker vs Faylor (Ind), 98 N E R 318)

The Appellate Court of Indiana, Division No 2, says that Section 520 of Burns' Statutes of Indiana of 1908 provides that physicians shall not be competent witnesses as to matters communicated to them as such by patients in the course of their professional business, or advice given in such cases This privilege may be waived by the patient, or those who stand in his place, or are authorized to represent him

The reason for this statute is that communications may be made in the relation of physician and patient which a due regard for the privacies and decencies of life should protect from being exposed to the public This privilege may be waived, and when the matters have been once published to the world, no reason remains to hold the privilege in force The statute was not enacted to enable persons to avoid liability or to win a suit by making it difficult to obtain evidence, but was made in order to allow them to prevent certain private affairs from becoming public property So it has been held in this and other states that, when a witness has been permitted without objection in a former trial to testify to privileged communications, the bar of privilege is waived, and the testimony cannot be excluded on that ground at a subsequent trial

In this case all the heirs of a Mrs Faylor sued appellant Studebaker to set aside a deed of conveyance of real estate made by her to the appellant, on the grounds that she was insane when the deed was made and the conveyance was obtained through fraud of the appellant On a previous trial a medical witness was permitted, without objection from any one, to testify to information gained while a professional relation existed between him and Mrs Faylor If the appellant would otherwise have had the right to object to the admission of the evidence on the second trial, such right was waived by failure to object at the former trial, thus permitting the communications to become public

Under authorities cited, the right to waive the privilege of confidential communications, after the death of Mrs Faylor, in litigation affecting her estate, was lodged in those who represented her and stood in her place It is generally conceded that heirs may waive this privilege The heirs or devisees seeking to overthrow a will may not waive it, however, as against other heirs or devisees It is unquestioned that the administrator has the power to waive the privilege in order to conserve the interests of the estate And, as before said, when once the matters ascertained in a privileged relation are published to the world without objection, no reason remains to uphold the bar of privilege

Cross Examination of Experts with Reference to Books

(Allen vs Boston Elevated Railway Co (Mass) 98 N E R 618)

The Supreme Judicial Court of Massachusetts sustains exceptions to a verdict for the plaintiff for personal injuries on account of error in the cross examination of a medical witness for the defendant because it says that the evidence thus obtained was plainly incompetent, coming, as it did, under the settled rule that neither medical books, though of recognized authority, nor the opinions of medical experts unless testified to by themselves as witnesses, can be received as evidence The court says that the cross examination was directed mainly to showing what the opinions of other medical authorities were as to the effect of the plaintiff's alleged injuries in causing the disease called "diabetes mellitus" On the defendant's first objection to a reference to a book written by Dr Davenport, the judge expressly ruled that the witness might be asked if certain authorities did not express certain views and if that did not change his opinion, although the judge said also that the jury were not to consider what was said in Dr Davenport's book The defendant did not then except, and the cross examination proceeded on the same line Finally the plaintiff's counsel asked whether the witness was familiar with any authorities which said that diabetes mellitus might come as the result of a blow, and the defendant then saved an exception (which afterward was renewed) to that line of examination The witness was asked also about books by Naunyn and Forchheimer, the questions being framed from a medical book written in German, which the counsel held in his hand The whole effect of the cross examination was to impress on the minds of the jurors the idea that certain writers were men of eminence in medicine, whose opinions were of value, and that their opinions differed from the opinion to which the witness had testified The objectionable cross examination, against the repeated objection and exception of the defendant, was continued so that, as reported, it covered more than five pages of the exceptions Similar questions were put in different forms as to different treatises, ending with general questions calling for and eliciting answers as to any text books that might agree with the claim of the plaintiff, and accompanied by the display of several medical books on the table of the counsel The effect and as may reasonably be supposed the purpose of counsel were to bring before the jury the opinions of others who were it was suggested, persons skilled in such matters, and to lessen the weight of the witness' testimony by showing that their views were different from his The court would hesitate to say that even a broad instruction to the jury to disregard wholly the evidence thus obtained would have cured the injury which had been caused to the defendant Justice required that there should be a new trial of the whole case

SOUTHERN MEDICAL ASSOCIATION

Sixth Annual Meeting held at Jacksonville Fla,
Nov 12 14 1912

(Concluded from page 2091)

The Surgical Importance of the Breast

DR. E DENEGRE MARTIN, New Orleans An important duty is the instruction of patients as to the care of the breasts The expectant mother or nursing woman should be taught how to care for the nipples, for infection through a fissured nipple will not only lead to abscess and sometimes to complete destruction of the gland, but also will leave scars to light up at some future time into inoperable carcinomas I have operated on more than 150 patients with cancer of the breast Three fourths of the cancers were in colored women and were already malignant when operated on I am not able to day to point out more than four colored patients who have lived over a period of six years Twelve white patients lived, the percentage being larger because they were seen earlier Every week we turn away from our clinics cases too far advanced for even temporary relief The surgeon who picks his cases will of necessity secure the best results, but the benefit should always be given to the patient, even if it means but a short prolongation of life The mortality from operations is less than 2 per cent, and in my operations, with 50 per cent of advanced cases the mortality is less than 1 per cent. These statistics are improving daily, as far as cures are concerned Still, the prevalence of cancer is on the increase, and we can and must reduce it

Extra-Uterine Pregnancy

DR J HUGH CARTER, Memphis, Tenn We should operate in all cases as soon as possible, as we never know when hemorrhage is going to take place, even if it has seemingly been stopped As to what operation should be done, I do not believe one can say until the abdomen has been opened Then the operator should do whatever he thinks best Each patient and the conditions found in the abdomen must be dealt with individually I would insist on a careful diagnosis of each case of suspected tubal pregnancy as early as possible, thereby giving the patient a much better chance for her life

Clinical Value of the Tuberculins in the Diagnosis and Treatment of Tuberculosis

DR WALLACE J DUREL, New Orleans In my personal observation of several hundred cases, it is evident that of eighty patients who were treated previous to 1909, of all those discharged as apparently well, and who were given the tuberculin test, the test proving negative, not one relapsed, yet many of the patients showed a distinct positive reaction on their discharge, and afterward relapsed, three dying since This evidence convinces me that repeated tuberculin tests will show whether treated and supposedly cured patients are free from any tuberculous focus, active or latent, regardless of its size or location, and that the negative reaction means more than a mere tox immunity in such cases

The clinical therapeutic value of the tuberculins is exemplified in the tabulated records of eighty cases of tuberculosis treated in Louisiana previous to 1909 In this report, in the first stage, 13 cases were treated, with recovery in all, and no relapse until 1912 In the second stage, 16 cases were treated, with recovery in 15, and arrest in 1 In the third stage, 30 cases were treated, 14 apparently well, and 16 arrested In 1912, 1 of the apparently well patients had relapsed, and 1 died. Of the arrested cases, 3 patients relapsed and 2 died Of the third stage 21 patients were treated, not one recovered, 9 were arrested, 10 were improved, and 2 non improved In 1912, 16 of the 21 patients have died These figures teach the practical lesson that the early-diagnosed cases of tuberculosis can be treated with far better and more lasting results than the advanced cases

Serum Treatment of Cerebrospinal Meningitis

DR. CHARLES C GREEN, Houston, Texas In Houston we had 182 cases with seventy four deaths, a death rate of 40 6 per cent, including those treated with serum and those treated without it Out of the total number of cases treated, twenty nine did not have the serum, consequently the death rate runs up rather high, twenty one deaths out of twenty nine cases giving the enormous death rate of 72 4 per cent, which, although high, is even lower than the usual death rate when the serum treatment is not used But of the 153 cases treated with serum, fifty three patients died, giving a death rate of 35.5 per cent, a reduction of 37 9 per cent in favor of the serotherapy I have taken the number of cases that had the serum within twenty four and thirty six hours after the onset, and our death rate in these was only a fraction over 20 per cent I believe that if all these cases could be treated by men who are familiar with this procedure, the death rate would be still lower

Gangrenous Tonsil

DR. U S BIRD, Tampa, Fla So rare is this disease that it is not a text book or reference book subject Five cases only could be found in medical literature, all of which were fata In addition to these I have knowledge of five cases, four in my own patients and one in the practice of a brother physician These [illegible], [illegible] mpared to the [illegible] ve [illegible]eviously reported, [illegible] first five cases [illegible] include two deaths but neither of these was due to gangrenous tonsil, which in these cases appeared to be an intercurrent condition, more or less due to the general depression that had rendered them vulnerable to such attacks In my fourth case only were operative measures indicated When a small area is involved and the general condition is good, instrumentation is indicated, but in great depression and extensive involvement, two conditions that seem to be associated, active interference may result unfortunately Only one of my cases is of interest in connection with pathology, the noma bacillus being present

Thrombophlebitis of Orbits by Ozena Bacillus, Death

Dr M Feingold, New Orleans I saw a girl, aged 15, who had an edema of the upper and lower lid, so extensive that the eye could not be opened voluntarily There was a hard infiltration through the upper lid to the depth of the orbit The temperature was about 101 F The patient denied that there had been any previous affection of the nose An operation was immediately performed, and an extensive focus of sticky, grayish, gelatinous pus was found and evacuated Necrotic bone was also discovered in the orbit The patient stood the operation well and spent a comfortable night The next day, however, pulse and temperature gradually rose and patient complained of pain in the head Probing revealed no further focus, but the edema on the right side had increased, and dilated veins were visible over the forehead and nose Atrophic retinitis was found in each side, with crusts and pus in the middle meatus under them On the following day the Killian operation was performed, and pus was found in the frontal and sphenoidal sinuses After the operation the patient gradually grew worse and died on the night of the following day The temperature had reached 106 1 F, with profuse perspiration and labored respiration The pus was found to contain a pure culture of *Bacillus mucosus capsulatus* No post mortem was obtained The interesting points in the case are the facts that a sinus affection may be latent for some length of time, and that orbital affection may be brought about by the affection of the adjoining nasal cavities

Diagnosis of Plague

Dr R L Wilson, Charleston, S C In plague work great care should be taken in handling infected animals, tissue, cultures and other material Even persons accustomed to bacteriologic laboratory work have to be reminded of danger, as several laboratory cases of infection are on record The principal things to look out for are fleas from animals, skin abrasions, soiling of fingers, using of pipets and smoking The principal points in diagnosis are (1) typical lesions, especially characteristic buboes, (2) production of the disease in animals by inoculation, (3) the unmistakable presence of the plague bacillus in smears, cultures and in inoculated animals

Symptoms and Clinical Diagnosis of Bubonic Plague

Dr J Birney Guthrie, New Orleans The appearance of the patient sick with bubonic plague is somewhat similar to that of one under the influence of alcohol The face is swollen, the eyes injected There is a general loss of coordination, with staggering gait and thick and stammering speech The speech disturbance frequently extends into convalescence, and with persistence of lymphatic enlargement and recent scars of suppurating buboes, may furnish the clew to identification of a previously unreported case The recognition of cases of bubonic plague where it is known to exist presents small difficulty to the physician It is the identification of the first cases, especially if they are of mild type which will present the severe problem in diagnosis In a suspicious case careful and continuous observation of the superficial lymph nodes should be maintained, and puncture with the needle and examination of aspirated fluid made by smears and culture methods

Finally the early identification beyond any doubt of bubonic plague depends on the microscope It is the duty of the attending physician to submit to the bacteriologic laboratory slides made from the fluid aspirated from every suspicious bubo and from sputum in every case of pneumonia showing more than ordinary depression at the outset, with a bright red sputum instead of the typical rusty sputum of ordinary pneumonia The services of the public bacteriologist should be available 'Possibly it might be wise to require the specimen to be submitted The only hope of limiting an outbreak is that of a prompt diagnosis of the disease To day every seaport of the world is menaced by plague, and the menace will be still further increased by the opening of the Panama Canal Therefore it becomes the duty of every one of us who practices medicine in a seaport to keep constantly in mind the possibility of encountering the disease To this end examination of the superficial lymph nodes during the progress of every acute febrile case becomes a matter of necessary routine

Treatment of Plague

Dr Isaac Ivan Lemann, New Orleans Our chief and first attention must be given to prophylaxis Several methods of producing active immunity have been proposed Haffkine, working in India in 1907, proposed his well known prophylactic. This consists of a bouillon culture of the pest bacilli, killed by heat and phenolized so as to represent a 0.5 per cent solution of phenol The dose of this varies from 0 5 to 1 c c, and in special cases as much as 20 c c are given The reaction varies greatly in different individuals, as a rule, there is slight fever, malaise, with local swelling, and edema for twenty four or forty eight hours Ten days later, a larger dose may be given, the size varying according to the reaction following the first dose The protection afforded by the prophylactic is not absolute When repeated several times it affords a relative immunity for some months From 4 to 20 per cent. of the inoculated contract the disease and from 2 to 8 per cent die. Passive immunization by means of serums derived from animals in which an artificial immunity has been created, has been used prophylactically and therapeutically The immunity produced by immune serums is said to last but a few days Aside from the specific treatment the management of a case of plague is entirely symptomatic Treatment is inaugurated with a brisk calomel purge followed by a saline The patient must be kept in bed in a well lighted, well ventilated room The diet throughout the acute stage should be liquid, principally milk and water with the addition of alcohol in cases in which there is great prostration Later a soft bland diet is permitted In convalescence regard must be paid to the probability of change having occurred in the heart muscle and in the kidney The buboes must be dealt with surgically

Resolutions Adopted

The resolutions which are summarized below were offered referred to the council, reported back to the association and adopted

NATIONAL DEPARTMENT OF HEALTH

President Elect Wilson's aid was asked "in securing the passage of the bill now before Congress to establish a department of public health which will elevate the importance of human well being to an equal plane with that of inferior animals, now protected by the almost paternal care of a 'Bureau of Animal Industry' "

MALARIA COMMISSION

Congress was "urged to create a commission for the investigation of malaria, with a view to recommending" measures 'efficient in extirpating the disease" "Such a commission should be amply provided with funds, and invested with liberal powers" "Details of medical officers of the Army, the Navy, and the Public Health Service should be at the service of this commission

PUBLIC INSTRUCTION

"Editors of newspapers and other periodicals published in the South, whether in town or country, are urged to join this crusade against the foes of health, happiness and prosperity by publishing gratuitously such articles and documents as will, in their opinion, advance the cause, and by the still more effectual means of editorial advocacy" A copy of this action was ordered mailed to every newspaper, magazine or other periodical within the geographic boundaries of the association

FEE SPLITTING

Whereas It is stated that among some physicians there has developed a pernicious custom of commercializing the most intimate and sacred confidences committed to their honor by referring their patient who needs special or expert treatment to specialists or surgeons who financially remunerate them for their reference either by paying a commission or by dividing with the regular physician their fees as specialists or surgeons and

Whereas It is prejudical to individual physicians and to the medical profession at large to allow such injurious rumors to circulate unproved or unchallenged and

Whereas It is the duty of our profession to protect the honorable position we have won by generations of faithful unselfish service therefore be it

Resolved By the Southern Medical Association that we earnestly condemn such dishonorable dealings on the part of anyone professing the high calling of medicine

Resolved That we urge all state and county medical organizations vigorously to oppose such dishonorable dealings and to appoint investigating committees whose duty it shall be to learn whether any of their members are thus dishonoring their calling and if any are so accused to summon them before a tribunal of their professional brethren to be acquitted or convicted of this crime against honor and humanity

Resolved That no guilty doctor whether donor or recipient of such a fee or commission in any way shape or manner should be allowed to escape a suitable penalty such as private reprimand temporary suspension or public expulsion

Resolved That these resolutions be spread upon the minutes of this association and that a copy thereof be forwarded by the secretary to every state and county medical organization within the geographic limits defining eligibility to membership in this association

14 Some Technical Methods for Routine Examination of Brain from Cases of Mental Disease S T Orton Worcester Mass

10 **Exciting Causes in Psychiatry**—The material of Rosanoff's study consists of 1,056 consecutive admissions to the Kings Park State Hospital Two hundred and seventy nine cases of imbecility, epilepsy, alcoholic psychoses, general paresis and other organic conditions are excluded from the study, leaving 777 cases In 66 9 per cent of these cases no cause has been assigned, and in 4 per cent conditions have been erroneously assigned as causes in more than half of the cases indications for commitment have arisen in the midst of an average environment and in the absence of occasion of special difficulty or strain In 7 1 per cent the psychosis has been attributed to alcohol the further study of these cases has been postponed In 2 6 per cent the psychosis has been attributed to other physical causes pregnancy, childbirth, lactation, traumatisms, surgical operations and acute infectious diseases In 16 6 per cent the psychosis has been attributed to psychical causes business troubles, death or illness of relatives, love affairs, domestic troubles, etc, and in 2 8 per cent to combinations of physical and psychical causes In one third of the cases in which pregnancy, childbirth, lactation traumatisms or surgical operations have been assigned as causes the relationship between the alleged cause and the psychosis is merely one of accidental coincidence in time there is no etiologic relationship

The remaining two thirds of the cases, however, leave no doubt of these factors being capable of causing insanity, although they do so infrequently In many cases the manner of their action is obscure owing to insufficiency of data in the clinical histories, wherever more detailed data are available it appears that these factors act not as physical causes but through their psychical accompaniments

Only in two cases out of a total number of 777 was the psychosis ascribed to acute infectious diseases, in one to typhoid and in the other to influenza In the first case the anamnesis was furnished by a feeble minded person and is not reliable it would seem that the duration of the psychosis prior to admission was much longer than it was said to be, probably dating back a long time before the attack of typhoid in the second case there is much discrepancy between the data obtained from the various sources, so that even the fact of the patient's ever having had an attack of influenza is not established Excepting febrile and infectious deliria, Rosanoff says the power possessed by the acute infectious diseases of producing insanity is at the most very slight and wholly questionable Leaving aside the matter of complete separation of personal and environmental factors, the exciting causes of the forms of insanity considered appear to be invariably of a psychical nature, and the cases in which no causes are assigned do not differ essentially from others in etiologic mechanism, it so happens that in their histories there is no spectacular event to be recorded as "the cause"

13 **Statistical Study of Manic Depressive Insanity**—During a period of ten years, 703 patients with manic depressive insanity were admitted to the Worcester State Hospital, out of a total of 5,706 patients constituting 12 per cent of admissions Of this number 309, or 43 per cent, have, as far as is known, had only one attack The fact that physical illness was found to be a cause in 24 per cent, or nearly one fourth of the first attacks of manic depressive insanity, Hoch points out to be significant, and of particular interest in the steady falling off of somatic causes in the succeeding attacks

17 *Chemical Nature of Certain Granules in Interstitial Cells of Testis R H Whitehead Charlottesville Va
18 *Comparative Study of Three Principal Regions of Spinal Cord in Series of Mammals. P B Bullard New Orleans
19 *Development of Cerebral Cortex E L Mellus Baltimore

17 **Chemical Nature of Certain Granules**—Whitehead concludes that the granules in the interstitial cells of the pig, and probably also of the cat, consist of a combination, either physical or loosely chemical of proteid with fatty material He also shows that the pig's interstitial cells, which contain no individual globules of lipoids, are no exception to the general rule that these cells, aside from any other function that may be ascribed to them, serve as a storehouse for fatty material

18 **Principal Regions of Spinal Cord**—This paper presents some observations based on the study of transverse sections of the three principal regions (intumescentia cervicalis, intumescentia lumbalis and middle of pars thoracalis) of the spinal cord in a series of twenty four mammals An outline drawing of a transverse section of the cords in each region is included together [illegible] tables of [illegible]rements showing variations in d[illegible] ruc[illegible] [illegible]ords mammals at

10 **Development of Cerebral Cortex**—It is the belief of Mellus that all mental development has an anatomic basis In a comparative study of the cellular structure of the so called "Broca's area" in the brains of three individuals there was found a very appreciable difference in the thickness of the cortical layers in favor of the left hemisphere It was almost impossible to say just where this difference lies The counting of cells in a cortical area is extremely difficult, although by no means impossible In many instances the count varies so considerably in contiguous areas of the same convolution, due sometimes to the presence of blood vessels and the doubtful nature of many of the cells, that it is difficult to arrive at satisfactory conclusions As a rule, however, it appears that the deeper cortex has the greater number of cells One would naturally suppose that a cortex increased in depth by increased functional activity would be due either to increase in the volume of the cells or separation of the cells by reason of an increase in the outgrowing or ingrowing processes, or both together From careful and prolonged study of the motor area in the human cortex Mellus is convinced that there are great variations in different individuals in the development of the largest elements, the so called Betz cells

25 *and* 27 Abstracted in The Journal, August 3, p 392

29 **Deformity in Volkmann's Paralysis**—The contracture in Ely's case was due to some of the deeper intrinsic muscles of the hand, and apparently also to the adhesion of new granulation tissue binding the long flexor tendoons to the front of the proximal phalanges of the fingers He found that when he passed the blade of the scalpel on the flat, close to the anterior surface of the phalanx, dividing these adhesions for a distance of about one half inch, he could easily reduce the contracture, but that until this tissue was divided the contracture could not be reduced The contracture of the thumb was due to a tight contracture of the flexor brevis pollicis and disappeared when this was divided

34 **Treatment of Tuberculous Joint Disease**—The authors report thirteen cases In all but one of these favorable results were obtained from Spengler's I K treatment

36 **Operative Treatment of Hammer Toe**—Merrill transplants the extensor tendons into the metatarsal bone to preserve the function of that muscle and prevent atrophy of it The muscle pull raises the metatarsal head and lessens the tendency to one feature in the mechanism of hammer toe and often relieves an associated metatarsalgia The flexors are implanted into the base of the first phalanx.

43 **Regional Muscle Rigidity and Degeneration About Thorax.**—From a diagnostic standpoint as to the presence of intrathoracic disease, most probably pulmonary, Pomeroy says that muscle spasm and degeneration is as definite a sign of those processes as similar phenomena in the abdomen In the hands of the expert clinician, one accustomed to the various phases of this problem, muscle changes over the thorax deserve careful study, and give reliable information that inflammatory changes or pathologic processes are to be found in the thorax, provided there is nothing in the peculiarities of the individual which would otherwise satisfactorily account for the signs It must be understood that regional muscle spasm, degeneration and reflex hyperalgesia may result from causes other than pulmonary tuberculosis, but with the limitations outlined in the paper The careful study of these phenomena is recommended to every thoughtful clinician

48 **Artificial Pneumothorax in Lung Tuberculosis**—This is Balboni's first paper of the series He discusses first the historical development of the treatment of tuberculosis by the establishment of an artificial pneumothorax by means of the injection of nitrogen gas, first proposed and practiced by Forlanini in 1882 What was done later in other countries is then discussed, finally the technic and preparation of the patient, the theories as to the action of the pneumothorax and the pathologic changes He has treated twenty one patients All except two are working and have kept at work continuously during the treatment

55 **Pertussis**—Whooping-cough, the authors believe, is due to a minute bacillus which occurs in large numbers between the cilia of the epithelial cells lining the trachea and bronchi and possibly also the nose The location of the organism is apparently characteristic for the disease Its action seems to be largely mechanical It interferes by its presence with the normal movements of the cilia and possibly leads to their destruction The mechanical interference with the action of the cilia, and possibly their destruction, prevent the normal removal of secretion The bacilli and the secretion produce a continuous irritation which results in coughing and usually also in the characteristic spasm known as whooping The bacillus found in the lesions by Mallory and Hornor, they believe, is probably identical with the organism discovered and described by Bordet and Gengou, but this identity remains to be demonstrated by the experimental production of the characteristic lesion in monkeys and puppies

56 **Origin of Giant Cell in Tuberculous Lesions**—Burgess reports the results of an experimental study of the origin of the giant cells which form around the fat like substance produced by tubercle bacilli The fatty material was injected subcutaneously into guinea pigs and the resulting lesions were studied microscopically at various time intervals In addition, for the sake of comparison, various other substances such as calcium salts, fat, fatty acids and cholesterin were injected in a similar manner and the lesions produced examined in parallel series of sections The results obtained are similar in character but differ in detail They all indicate strongly that these foreign body giant cells originate in only one way—by fusion of endothelial leukocytes

57 **Chloroma**—It is held by Burgess that the tumors to which the term chloroma has been applied do not constitute a pathologic entity On the contrary, they represent a part of the pathologic process in one type of acute myelogenous leukemia Chloroma has not been shown to have any relation to true lymphatic leukemia Myelogenous leukemia is a blood metastasis of a true tumor whose origin is in the bone marrow and whose cells invade the blood stream and bone marrow In certain cases in which the cells are, most of them, relatively undifferentiated and multiply rapidly, other tissues are invaded. Sometimes in this way definite nodules or masses of tumor cells are formed These masses, if green are called chloroma

58 **Pleomorphic Bacillus with a Streptothrix.**—The organisms that form the subject of Williams paper were obtained from a case of tuberculous pericarditis A bacillus and a streptothrix were encountered growing together in a mixture Under certain conditions they resembled each other closely, and nearly led to the belief that one might be transformed into the other Eventually they were separated by plating, and in pure cultures each retains its characteristic properties The bacillus develops into long filaments, with occasional branches, in media containing 1 per cent of dextrose The streptothrix produces single oval spores at the ends of the threads or branches resembling spore formation in some species of bacilli, including the bacillus with which it was associated as above mentioned.

59 **Complement Fixation in Tuberculosis**—The complement fixation test with antigen derived from tubercle bacilli is believed by Laird to be at present of comparatively little diagnostic value It is quite probable that it may be of more aid in diagnosis if better antigen is devised and certain disturbing factors are eliminated Even in the present stage of the development of the test sharply positive reactions are obtained at times and the quantitative study of the various phenomena connected with the presence or absence of such reactions, especially when correlated with clinical findings, promises results of some value in studying the course of the disease The more general use of the Wassermann test for syphilis in institutions for tuberculous patients, he believes is desirable not only for the aid it gives in clearing up a doubtful diagnosis, but also for the purpose of studying the relations between the two diseases

Eighty five tests with the sera of thirty four patients the antigens used being derived from tubercle bacilli, gave complement fixation in twenty four tests These positive results were obtained with the blood of four patients The blood serum of a patient in the moderately advanced stage of the disease, was tested on four different dates and each time gave a completely positive result On May 3, 1911, different dilutions of his serum were tested and complete fixation was obtained with 01 c c of the serum Again on June 28 1911, complete fixation was obtained with 05 c c. of his serum, no higher dilutions being used at this time The patient was doing well during the period covered by the tests. He began taking tuberculin on Sept 5, 1911, which was four weeks subsequent to the first test, and on June 28, 1911, the date of the last test, he had reached a dose of 00068 grm B F Co (a mixture of B F and B E given at the Adirondack Cottage Sanitarium) He was discharged with disease "arrested" The serum of a patient in the moderately advanced stage of the disease without tubercle bacilli in his sputum, was tested on four occasions He had been taking tuberculin treatment since Nov 22 1910 (S.B E) The first two tests were negative On March 7, 1911, the patient had a severe general tuberculin reaction in the course of treatment and on April 20, 1911, his blood gave a completely positive reaction On June 28 1911, this could no longer be obtained He was admitted as a moderately advanced case and was discharged after nine months an "apparent cure" The highest dose of tuberculin reached by him was S B E 0032 c c

The two other positive reactions were obtained on July 7, 1911 from the blood serum of patients who were in the moderately advanced stage of the disease and had tubercle bacilli in their sputum Both were taking tuberculin, but had received only small doses, less than 0000001 gram of O T and B F respectively One was discharged "improved" and the other with 'disease arrested" Beside these tests in which complete fixation was obtained there were a number in which there was partial fixation Complete hemolysis was obtained in sixteen of the tests, although the antigen used alone in the same dose (without the patient's serum) had shown some anticomplementary action This is the so called "inhibitive" reaction of Caulfield, which he believes is characteristic of certain favorable cases or of cases doing well at the time of the test Seven of these sixteen "inhibitive" reactions were obtained with the serum of a healthy control, the remainder were from four patients with moderately advanced disease who were doing well at the time of the test

60 **Experimental Typhoid Carrier State in Rabbit.**—The following summary is made by Johnston The condition analogous to the typhoid carrier state in man can be produced in the rabbit *B typhosus* can be recovered from the blood up to the end of the first month and longer following inoculation and from the feces up to 110 days *B typhosus* can be recovered from the bile approximately from thirty to sixty days after inoculation, and would then seem to become attached to the gall bladder wall, since post mortem examination revealed the presence of *B typhosus* in the gall bladders of nine of eleven unvaccinated animals examined, and no typhoid organisms could be found in the gall bladders of five vaccinated animals so examined An inoculated animal becoming a carrier may have a reappearance of the typhoid organisms in the stools due to a catarrhal condition affecting the gall bladder From the results obtained in this experiment, vaccination would certainly seem to be indicated as a means of treatment in the human carrier, and also as a prophylactic agent in the prevention of such carriers A routine examination of the stools and urine of all typhoid convalescents should be required by municipal health authorities until successive cultures are negative, as is at present the practice with cases of diphtheria

63 **Fluid for Standardization of Vaccines.**—Counting the bacteria in the hemocytometer is the method proposed by Callison For more than two years he has used the following diluting fluid, w [illegible] ed to be so satisfactory

Hydroch' [illegible]	2 cc
Bichlo [illegible]	c
Acid	

His instructions for carrying out his method are as follows

A drop of the filtered solution is placed on the ruled stage of the hemocytometer, covered with a coverslip, and examined with a 4 mm objective The color should be just deep enough not to obscure the ruling If the color is too deep, filter again, as each filtration removes some of the fuchsin If not deep enough, add more fuchsin solution Using the red dilution pipet, draw up the bacterial emulsion to the 5 or 1 mark, and the diluting fluid to the 101 mark Shake vigorously for three minutes, allow two or three drops of fluid to run out of the pipet, then deposit a small drop on the stage of the hemocytometer Cover with a polished glass coverslip and set aside half an hour for sedimentation to occur Make the count with a small diaphragm and a strong light Keep the small square being counted well in the center of the microscopic field Before counting, focus up from the ruled lines to ascertain if all the bacteria have settled on the ruled stage Make the count and the subsequent calculation as for red blood cells The bichlorid forms a mercury albuminate on the surface of the bacteria and causes more rapid sedimentation, the hydrochloric acid keeps the whole in solution, and the acid fuchsin stains the bacteria, making them more visible

94 *Disinfection of Intestine by Insufflation of Oxygen M Cross New York

82 **Calorimetric Observations**—The results of Lusk's experiments with a dog lead him to the general conclusion that there exist the following forms of metabolism in the quiet or sleeping dog excluded from thermal influences 1 A basal metabolism when the cells are nourished by a blood stream which does not receive food from the intestinal tract and the composition of which is regulated by the organs of the body 2 A metabolism due to plethora induced by an increased quantity in the blood of carbohydrate or fat metabolites which are being absorbed from the intestine 3 A metabolism due to the stimulus of incoming amino acids acting on the cells

The metabolism of plethora and the metabolism of amino acid stimulation cannot be added to each other, there is no summation of effect when both influences are brought into action together In other words, cellular activity induced by the presence of carbohydrate is not further intensified by the stimulus of amino acids unless the latter alone would accomplish the result The height found for the basal metabolism of the perfectly quiet resting organism excluded from thermal influences and determined eighteen hours after the ingestion of food, confirms Rubner's law of skin area, but places the heat elimination at a lower level

As a practical conclusion of these experiments it appears that in a quiet and resting animal the heat production is increased by about 20 per cent after the ingestion of a mixed diet and this increase continues during the period of intestinal absorption also addition of moderate amounts of protein to the diet has little effect on the production of heat even though this protein given alone would of itself cause a considerable rise in the heat production Hence, a mixed dietary is physiologically economical

94 **Disinfection of Intestine by Insufflation of Oxygen.**—Ad Schmidt introduced oxygen directly into the small intestine by means of the duodenal tube ' and the results he reported were very favorable Cross has adopted the following procedure for the oxygen insufflation His duodenal tube is introduced in the morning on an empty stomach down to mark 90 cm which means about 30 cm beyond the pylorus This so called deep exploration is particularly desirable for the present purpose as it prevents the return escape into the stomach of too large quantities of oxygen The outer end of the duodenal tube is now connected direct with the regulator of an ordinary oxygen jar, and the gas is allowed to flow slowly in From time to time when the patient complains of distention the influx is interrupted In this way he has been able to administer any desired quantity of oxygen He endeavors to apply a kind of continuous gas bath" which may last from 1½ to 2 hours Instead of making two insufflations a day as advised by Ad Schmidt Gross allowed in one case the tube to remain in situ from morning till evening and administered the second insufflation in the evening In the meantime the patient received liquid food per os not through the tube Expulsion of odorless flatus could often be observed during the administration, showing that the gas had passed the ileocecal valve

110 *Diet in Carcinoma F G Kessler New York
111 Postyen and Its Natural Hot Sulphur Mud Baths F Ilsko New York

110 **Diet in Carcinoma**—The proteins of the meat diet are all rich in sulphur and in Kessler's opinion ought to be reduced However, he would not go so far as to recommend an exclusively vegetarian diet in carcinoma A vegetarian diet would certainly not according to his opinion, be sufficient for good nourishment with the high rate of waste in carcinoma Proteins with a low percentage of sulphur are the caseins of cow's milk It would also be desirable to reduce the lactalbumin of cow's milk and to use the pure casein Conversely one must exclude a number of vegetable foods that contain a high proportion of sulphur To prevent cancer or metastases on the lips or in the mouth smoking ought to be stopped In smokers the production of sulphocyanic acid is increased Sulphocyanic acid is a compound of neutral sulphur It diminishes the oxidation of sulphur Most likely Kessler says, this is to be attributed to the influence of the nicotin The diet which he would recommend in carcinoma would be somewhat of the following scheme, to be modified according to the taste of the individual

Breakfast Tea or coffee with sugar and cream (not milk on account of the lactalbumins), little bread with much butter fresh or cooked fruit

Dinner Soup of fruit or cereals or vegetables (not meat broths), peas, lentils, beans, for change meat, 2 ounces at the most purée of potato dumplings edible roots (carrots, beets), boiled or preserved fruits, rice salads

Supper Fruits with rice, potatoes with butter, salads

The nourishment should be plentiful The necessary quantity of casein, 1 or 2 ounces can be mixed with butter and used with the various meals The casein can also be added to the various soups purées of potatoes, and to the dishes of vegetables during the process of cooking In order not to cause any aversion of the patient to the casein it must be absolutely pure and tasteless A flavoring addition to the casein of stewed tomatoes and the like is also permitted The casein may also be given in the form of a medicament, in dry powder in one half to 2 dram doses, every three hours, between meal times, and is best taken down with a swallow of water

116 **Head Surgery in Epilepsy**—There can be no question says Munson that in the past there has been much ill advised and indiscriminative operative intervention in the epilepsies, and some of the cases, viewed either from the purely surgical point of view or from the standpoint of the epileptologist are sad commentaries on the ill judged activity of the surgeon He reports nineteen cases in which some surgical intervention was undertaken on the head, and which afterward came to autopsy In some cases the scar tissue formation has been the evident cause of continued irritation and in others there was cerebral destruction which was sufficient to cause the attack, but in others there was apparently both a successful operation and an absence of lesion Why, then asks Munson, the ill success? He has frequently expressed his idea of the origin of epilepsy as an equation in which the sum of a varying number of known unknown and variable quantities is placed equal to the seizure, i e causes the seizure It would appear from this that the etiology of any case was a summation and therefore unless one of the etiologic quantities was decidedly greater than the others, the treatment of any one of them would not cure the case Munson believes that this is true In looking over the cases which have been made the subjects of operation, there is found for example, a decided neuropathic taint in many of the family histories and if this is to be accepted as an important etiologic quantity, one must admit that it cannot be excised along with some focal lesion or drained away by a drainage and decompression operation Similarly some patients who desire operation have alcoholism or venereal excesses as part of their etiologic equation There again the knife is handicapped In some of the traumatic cases the trauma is not the cause, but is the result, of the first seizure and therefore the operation is of secondary importance

117 **Surgical Intervention in Epilepsy**—Out of the total number of 3,502 patients admitted to the Craig Colony for Epileptics forty eight had been trephined either before admission or during their treatment at the Colony In a few of these the operation had been repeated Naturally none of the patients operated on at the Craig Colony have been trephined immediately after a trauma or the onset of the epilepsy, as they were all confirmed epileptics at the time of admission The results of operation on these patients cannot be compared with those obtained by operation immediately after the trauma or in the early stages of the epilepsy None of the patients trephined at the Colony have been permanently relieved from the attacks although most of them were benefited, at least temporarily by the operation In several cases in which operation was done before admission, the condition of the patient had been made worse by the operation as was stated in the histories at the time of admission In some of these cases the relationship to trauma or focal irritation was very remote or questionable the slight trauma to which they were attributed acting merely as an exciting cause in a susceptible individual Some of the trephined cases were done for conditions other than traumatism Convulsions following encephalitis or meningitis may be considered as epilepsy due to gross brain lesions Operation is indicated in those cases in which a Jacksonian type of seizure suggests a focal lesion Unfortunately for the operative results such a lesion may not be limited to the Rolandic region nor even situated in this area, but in one of the surrounding lobes or deeper structures and produces the convulsions by irritation of the motor area As a general rule the more a convulsion is limited to one extremity or part of an extremity, the more localized is liable to be the cortical irritation and the greater the chances for arrest of the seizures by removing this focus When a definite injury to the head has been sustained if of such a nature that fracture or hemorrhage is suspected Sharp says it is better to operate at once and remove clots depressed bone etc before the irritation leads to epilepsy for unfortunately the convulsions once started may persist as confirmed epilepsy even after removal of the exciting cause When epilepsy has already developed as a result of trauma to the head a single operation may produce arrest of the attacks In some cases in which the attacks have ceased for a year or two following the operation and then return it has been the custom with some surgeons to trephine again Sharp's observation is that if the first operation with a fair amount of decompression, does not produce relief it is useless to repeat the surgical measures

9 Influence of Meteorologic Conditions on Development of Trypanosoma Rhodesience in Glossina Morsitans A Kinghorn and W Yorke

1 **Crude Phenol as Larvicide in British Guiana**—The authors are inclined to the belief that, in the case of a temporary small collection of water, if crude phenol is applied it does not evaporate to any large extent but concentrates as the puddle dries up, and further, that, having dried up, the ground is sufficiently impregnated with the phenol to render water deposited later by a shower of rain fatal to larvae Sufficient data have, however, not yet been collected to make an authoritative statement on this point Laboratory experiments showed that a dilution of 1 in 20,000 is efficient as regards all larvae inside two hours, but in the case of pupae a much longer time is required, probably owing to the fact that the pupa possesses a thick chitinous shell and has no alimentary canal into which to take the poison For use they calculate one teaspoonful to every 2 cubic feet of water or 1 ounce to 16 cubic feet, this gives a dilution of about 1 in 16,000, and allows a fair margin of safety to cover errors in calculation The crude phenol containing all its impurities is much more efficient than the purified, more highly soluble product

6 **Urriola's Test for Malarial Infection**—Sinton does not believe in the value of Urriola's test (discovery of malarial pigment in the urine) He says that it is almost impossible to exclude the possibility of the pigment derived from extraneous sources finding its way into the urine, and therefore the presence of small quantities of fairly large masses of pigment appears to him to be of no diagnostic value The trouble necessary to exclude the possibility of extraneous pigment appears to be too great in comparison with the value of the test As far as can be concluded from the few patients examined by Sinton, the presence of pigmented leukocytes or casts appears to be of more value than free pigment in making a diagnosis of present or past malaria, especially in chronic cases The presence of pigmented leukocytes or casts does not seem to be an indication of act[illegible] the fact that the patient has [illegible] ve malaria but rather of malaria Two of his pati[illegible] at some time or other had being discharged as cure[illegible] of malaria for two ye[illegible] nts were examined just before leukocytes The p[illegible] One of them had had no signs ably represents [illegible] s yet both patients showed pigmented infection and [illegible] sence of such pigment in the urine probably [illegible] an attempt by the body, both during an [illegible] after the infection has passed off, to get rid of the pigment deposited in the tissues

13 **After-Results of Operations for Tuberculous Joints**—During the ten years from 1901 11 Stiles has done sixty three excisions of the knee for tuberculosis and of these thirty eight have been traced In twenty three of the patients there was osseous as well as synovial disease, the former being sometimes in one bone, but in the majority of cases in both Healing by first intention resulted in fifty three cases, while in nine cases the wound broke down or recurrence set in within a month after operation Twelve out of the sixty three patients required a subsequent amputation, and of these nine were under 5 years of age Of thirty patients who have been traced and recently examined, there was absolute ankylosis in twenty nine and slight movement in one case. In twenty seven instances there was a little flexion, the leg was absolutely straight in one case, and in a position of genu recurvatum in two cases

He has done fifty nine excisions of the hip and of these forty cases have been traced In fifty three there was osseous as well as synovial disease, the former being sometimes in one bone, but in the majority of cases in both Usually, however, the disease was too far advanced to say whether the disease in the bone was primary or secondary With regard to the mode of excision, the anterior route was employed in only eight cases, nearly all of which were among the early series, four were done by an external incision and the remainder by Kocher's postero external angular incision, this method being employed even in cases in which there was an anterior abscess Forty eight patients were discharged with the wound completely healed and the limb maintained in the abducted position by means either of plaster of Paris or an abduction splint In three cases disarticulation of the hip was subsequently performed on account of recurrence of the disease, followed by sinuses and hectic fever, one of these patients died four days after operation Five patients returned with slight recurrence of disease necessitating further operation Forty three patients were found to be well, and with the limb in good position when they returned from two to six months later to have the plaster removed Out of forty cases traced there were twelve deaths, two died in hospital of tuberculous meningitis, nine died within six months of general tuberculosis and the twelfth eighteen months later from the same cause The results were good in nineteen cases, that is to say, the general hea[illegible] excellent, the hip ankylosed no sinuses, the scar[illegible] decolorized and any shortening, adduction or [illegible] flexion only ver[illegible] moderate

[illegible] excisions of the elbow The rig[illegible] elbow was affected in thirty two instances the left in twent[illegible] two the difference being due, probably, to the greater use [illegible] the right arm In 67 per cent of the cases the disease beg[illegible] before the age of five years, while in 32 per cent it show[illegible] itself within the first two years As a result of this ear[illegible] age incidence a relatively large proportion (55 per cent) [illegible] the excisions were done in children under 4 years of age [illegible] fourteen cases the disease was primarily synovial, in t[illegible] remaining forty one or other, or all three, bones were a[illegible] involved The humerus was involved in twenty cases, t[illegible] ulna in thirteen, the radius in three, while in eight cases m[illegible] than one bone was involved Of the fifty four excisions of t[illegible] elbow thirty four have been traced. Of these, six patie[illegible] died subsequently of general tuberculosis from three mont[illegible] to two and a half years Some degree of local recurre[illegible] occurred in eight cases, one of which fails to be classed am[illegible] the deaths Only one required subsequent amputation [illegible] the remaining six the recurrence took the form either of [illegible] abscess or sinus, with slight disease in the subjacent bone [illegible] all of these healing was brought about by a comparativ[illegible] trivial secondary operation.

Of twenty nine cases of tuberculous disease of the ankle joint operated on during the decennium mentioned, the disease was primarily synovial in six cases, while in twenty three cases it was both synovial and osseous. The astragalus was involved in fifteen cases, the os calcis in five, the tibia and fibula in two and the scaphoid in one. In those cases in which it was manifest that the disease was osseous in origin, the primary focus was almost invariably situated in the head or neck of the astragalus. In thirteen of the patients the disease began in children between 2 and 4 years of age, while in twenty one out of the twenty nine cases the operations were performed on children between 1 and 4 years of age. Twenty five patients have been accounted for. Two died within three months of operation. One, who had also hip joint disease, died a year later from general tuberculosis. In six cases amputation was subsequently performed for recurrence of the disease.

21 **Tuberculous Infection and Tuberculous Disease in Infancy and Childhood.**—Tuberculous infection, according to Lapage, almost inevitably is in large towns and it must often occur in childhood without giving rise to illness sufficiently pronounced to attract attention, or the indefinite illness, if noticed, is put down to some other cause, such as rheumatism or underfeeding. Occurring at an early age, tuberculous infection often leads to fatal results, but later in childhood it may lead only to a temporary debility and then become quiescent. Such quiescent disease, which can only be diagnosed from the history, the Roentgen ray examination, and the tuberculin test, is not infectious, and since it is so wide spread it is not necessary to notify every case that gives a reaction to tuberculin. To do so would be to overwhelm those engaged in preventive measures and to stultify their efforts. Tuberculous disease in children is very different from that in adults. All through childhood it tends to become generalized and a large proportion of the deaths are due to tuberculous meningitis. The glands are often affected and the disease may make considerable progress in them before it spreads to other parts or gives localizing symptoms. Therefore we must not look for definite physical signs before making a diagnosis of tuberculous disease. Lapage relies on the history, the general symptoms and the special methods of diagnosis to begin treatment early.

36 **Sarcoma of Long Bones.**—In one case of [illegible] of the tibia Eve united the femur and tibia by bolting them together with a portion of the patient's own fibula, a gap of nearly [illegible] inches being left between them and the limb thereby lengthened. Later skiagrams appeared to show that there was a new formation of bone beneath the periosteum of the [illegible] fibula. It is now a year and seven months since the [illegible] there is no recurrence and the patient can walk with a [illegible] plastic support, but the union is not firm and the shortening amounts to 4½ inches. Eve says that when autoplastic grafts are used the periosteum of the graft should be preserved. Eve is convinced that a certain number of sarcomata disappear under, or are profoundly influenced by, the Coley toxins, but says we have no means of determining what proportion this is to the total number treated. He believes it is only a small proportion. His present attitude is that he would not recommend Coley's fluid in any case of operable sarcoma, nor would he recommend it as a prophylactic against recurrence.

39 **Mitral Stenosis and Renal Fibrosis.**—The relationship between the two lesions, according to the authors, may conceivably arise in various ways. It may be accidental, the renal lesion may be the cause or the result of the mitral disease, or both may own the same origin. Figures quoted seem sufficient evidence that the association is not simply accidental, for Newton Pitt found that mitral disease is three times more frequently present in cases of granular kidneys than when kidneys are normal, and in the author's series the proportion is even greater [fibroid kidneys, 335 cases, mitral disease, 60 (17.9 per cent.) Kidneys not fibroid, 807 cases, mitral disease, 33 (4.0 per cent.)]. There is no doubt that the majority of cases of mitral disease are the result of an antecedent acute endocarditis of rheumatic origin. They have collected a series of 479 cases of organic mitral disease and in 27[illegible] (57.4 per cent.) the patients had suffered from some form of rheumatism or from chorea.

In a small number of cases of mitral stenosis no recognized cause of acute endocarditis can be discovered in the antecedent history, and in another group it seems unlikely, from the history of the case, that such causes, though they had been present, could be associated with the origin of the valvular lesion. It is generally agreed that the most frequent causes of these chronic cases are arteriosclerosis and chronic nephritis, and in three cases seen by the authors, the kidneys were more or less granular and the capsules adherent. It thus seems evident that in some cases the renal lesion is the cause of the cardiac one, but it is improbable that this is the common sequence. It is true that the incidence of mitral disease in cases of renal fibrosis is much greater than in cases where no renal fibrosis obtains, but the incidence is much greater in women than in men, a fact which suggests that the connection arises in other ways. The post mortem evidence makes it fairly evident that renal fibrosis cannot be the cause of mitral stenosis in all the cases in which the two lesions co-exist, and the inference is strengthened by examination of the clinical data. The evidence seems to show that mitral stenosis and renal fibrosis may own the same cause.

40 **Triple Rhythm of Heart.**—It is suggested that the rhythmical production of [illegible] at an abnormally irritable [illegible] in the ventricles may produce these [illegible]

41 **Diagnosis of Sinus Arhythmia.**—[illegible] that irregularity of the heart in children during convalescence from febrile illness is common. [illegible]

mechanism is normal, sinus arhythmia, a form of irregularity which is devoid of any pathologic significance whatever. The frequent occurrence of sinus arhythmia after acute illness in children is not generally known to practitioners, and the irregularity is confused with those of pathologic origin. Its recognition is important, otherwise the patient is needlessly kept in bed and subjected to unnecessary treatment until it becomes manifest that the irregularity is a negligible symptom. While, as a rule, the diagnosis of sinus irregularity is readily made on clinical examination, exceptionally it is only established from records of the heart's movements and respiration. The cases described in the paper illustrate possible fallacies in the *interpretation of tracings*.

42 **Origin of Premature Heart Contractions.**—The electric curves of premature contractures obtained by the authors in repeated examinations of the same patients show a remarkable constancy of outline, this fact is regarded as evidence of the constancy and limitation of the focus of irritation in which they are produced. There are facts which suggest but do not allow them to conclude finally, that premature ventricular contractions arise, as a rule in the special tissues which unite the auricular and ventricular musculature.

43 **Variations of Blood-Pressure.**—It is stated by the authors that in lumbar puncture the puncture of the skin is accompanied by a rise in blood pressure which varies in extent with the degree of consciousness the pain, and the disturbance produced by the operation, but which is not accounted for entirely by these factors. Withdrawal of cerebrospinal fluid tends *per se* to lower the blood pressure, but the net result of lumbar puncture is to raise it for at least twenty minutes afterward. The type of blood pressure chart obtained in lumbar puncture when the increased intracranial pressure is of subtentorial origin, is the same as that obtained in normal individuals, or as that obtained when the increased pressure is of supratentorial origin but in the subtentorial types the variations are less pronounced. In subtentorial cases the rise is more sustained. Blood pressure records from cases of high spinal anesthesia show at the outset an abnormally high blood pressure due to mental anxiety then a rise following lumbar puncture next a 'preliminary fall" followed by a further more marked 'main fall" as the paralysis affects the thorax. Finally, as the paralysis passes off, the blood pressure rises to its original value. Variations in the pulse rate do not closely follow those of the blood pressure but a certain degree of resemblance is often seen owing to the consciousness of the patient. Vomiting during spinal anesthesia is due to thoracic paralysis. In the supine position there is no stagnation of blood in the great vessels, even when very high spinal anesthesia is induced.

46 **Sinus Arhythmia of High Grade Induced by Digitalin.**—Three cases are described by Laslett which developed sinus arhythmia of high grade under the influence of digitalin. Two of the cases had a preexisting impairment of conductivity notwithstanding which the grade of heart block was not increased by digitalin so far at least as to cause ventricular silences. The first case exhibited an unusually well developed two peaked presystolic wave in the jugular pulse. The first wave was undoubtedly and the second probably auricular in origin. The peculiar form of the wave is regarded as evidence of hypertrophy of the right auricle. The third case showed an extreme sensitiveness to the drug which it is suggested, may have been in some way related to the fact that the auricles had just previously been in a state of fibrillation.

47 **Auricular Fibrillation.**—A case is recorded by Lea of auricular *fibrillation associated with a high degree of auriculo* ventricular block and with attacks of paroxysmal tachycardia of (probably) ventricular origin.

54 *Old Spina Bifida. F Tournier and J Ducuing.
55 *Dermoid Cysts of the Mesentery. J Pakowski.
56 *Fascia Lata Flap for Dura Repair. (Plastiques dure meriennes avec le fascia lata.) L Mauclaire.

54 **Old Spina Bifida.**—Tournier and Ducuing report ten cases which sustain their statements in regard to the indications for operative treatment, that is, excision of the tumor when it is complicated with nervous symptoms of no longer than a year's duration at most or when the tumor is free from complications but is of annoying size. When the nervous symptoms are of long duration palliative treatment should be the rule, some orthopedic operation elsewhere than on the spina bifida offering the only prospect of benefit. Under all other conditions operative treatment is contra indicated.

55 **Dermoid Cysts of the Mesentery.**—Pakowski summarizes thirty cases from the literature classifying them according to the location of the cyst and discussing treatment. The preferable technic is removal of the cyst but the clinical experiences and his own experimental research show that it is necessary to resect the segment of intestine if the circulation has been impaired by the excision of the cyst.

56 **Fascia Flap for the Dura Mater.**—Mauclaire reiterates that the fascia lata is peculiarly adapted for repairing defects after herniotomy and in the dura mater reporting a case in which it was used for the latter purpose and reviewing the literature on the subject.

Bulletins de la Société de Pédiatrie, Paris

October XIV No 7 pp 12 400

57 *Administration of Salvarsan by the Rectum in Children. (L absorption rectale des arséno aromatiques chez l enfant.) A J Weill Morel and C Mouriquand.

59 *Diabetic Boy of 8. (Exposé d un cas de diabète infantile.) P Merklen.
60 *Pyopneumothorax and Pleural Gurgling. (Pyopneumothorax et bruit du glouglou pleural.) J Renault and P Lévy.
61 *Enlarged Thymus Returns to Normal Size Under Roentgen Rays. Three Cases. E Albert Weil.

57 **Absorption of Salvarsan by the Rectum.**—Weill reports three cases in which he was able to demonstrate the absorption of salvarsan from the rectum of children between 10 and 13. The technic was the same as for intravenous injection, with addition of 5 or 10 drops of laudanum. The rectal injection was given as slowly as possible the rectal catheter introduced deep and the injection retained for four hours at least. He did not see any evidence of local or general by effects and he thinks this route is peculiarly advantageous for children.

58 **Uremia in Infants.**—Nobécourt states that urea was found in the cerebrospinal fluid in thirty nine of eighty nine sick infants in his service. Whenever the proportion of urea was over 0.5 gm per liter the children all died in less than a month. In some cases the uremia causes a clinical picture resembling that of the somnolent form of tuberculous meningitis except that there is myosis and no lesions in the fundus of the eye, mydriasis is more common in meningitis. Another difference is that in the uremic the pulse persists regular and is not much accelerated in meningitis the pulse is extremely irregular while the respiration is but slightly modified. In *uremia the respiration is very abnormal* even a Cheyne Stokes type being common. The gastro intestinal disturbances with uremia frequently subside but in both uremia and meningitis there is the increasing somnolency with progressive emaciation. In the two cases described the infants were under 3 months old while meningitis is rarely observed so young. Decisive evidence is afforded by lumbar puncture urea will be found present in large amounts from 0.51 to 3.15 in his cases, in meningitis in infants he never found over 0.25 gm.

59 **Diabetes in a Child.**—Merklen gives the metabolic findings systematically recorded through nine months in a case of diabetes in a boy of 8 No treatment proved durably effectual and the child died finally in coma

60 **Pyopneumothorax.**—Renault reports a case which confirms the importance of the single bubble sound as a sign of pyopneumothorax in a child The sound is elicited by placing the child in a jack knife position on his hands and feet with his legs stiff the buttocks very high the head close to the legs The chest of the child is then lifted up until he stands erect during which auscultation will reveal a single sound as an air bubble makes its way from below upward and bursts at the surface of the fluid Repeating the maneuver brings the sound anew each time This sign of the fluid and air accumulation may be evident before there is anything else to suggest its presence

61 **Roentgenotherapy for Enlargement of the Thymus**—Weil calls attention anew to the remarkable efficacy of Roentgen exposures in reducing the size of an abnormally large thymus His four cases bring to eleven the number on record in all of which the measure proved successful He does not apply large doses finding the mild amply sufficient There was no further trouble forty eight hours after exposure to from 1 to 5 H units, with a filter, 18/10 He does not think it necessary to do more than reduce the size of the thymus it is not necessary to destroy it altogether His patients were infants between 2½ and 9 months old The number of exposures ranged from five to twelve as a rule, although Meyer gave forty seven very mild exposures in his case

Presse Médicale, Paris

November 6 XX No 91 pp 921 928

62 *Improved Technic for Operative Relief of Gastric Crises etc Excision of Spinal Ganglia (Ganglicetomie rachidienne dorsale) J A Sicard and E Desmarest
63 Hemolysis in Tuberculosis (Anémie hémolysinique tuberculeuse) E Weill C Gardère and A Dufourt

62 **Excision of Spinal Ganglia**—Sicard and Desmarest give an illustrated description of an operation which breaks the continuity of the spinal nerves as by the Förster and Franke methods while it seems to be free from their uncertainties and the possible dangers of both They insist that if the Franke operation is done in a way to be harmless it fails to accomplish its purpose, while if it is thoroughly done it is dangerous Dejerine has reported a death on the table from double pneumothorax occurring during a Franke operation and they have had a similar fatality in their experience An illustration of the findings on the cadaver show that the operation acts more on the anterior than on the posterior roots of the intercostal nerves and thus fails largely of its purpose The technic proposed is to resect the ganglion after laminectomy not opening into the dura mater it is thus an extradural spinal ganglieclomy It is applicable only to the intercostal nerves and laminectomy in the dorsal region they regard as comparatively simple The nerve in its dura mater sheath is ligated with O silk close to the spinal cord and the nerve farther along is seized with forceps The nerve in its intact sheath is then cut with scissors close to the ligature, and the other end is torn loose by twisting it up gently on forceps The nerve tears beyond the ganglion which is thus brought away whole entirely outside of the dura As the ligature is drawn tight the patient may stop breathing and the pulse grow faster, but these reflex phenomena last only a few seconds The various steps of the operation are illustrated and a case described in which it was successfully applied The patient was a man of 44 with tabetic gastric crises lasting two or three weeks at a time and recurring about every two months He had been clamoring for operative relief of some kind for two years, and the above technic was applied last July After laminectomy from the fifth dorsal to the ninth dorsal vertebrae the epidural space was freed from fatty tissue and the ligature was thrown around the seventh left intercostal nerve between the cord and the ganglion The ganglion was then excised by cutting the nerve above and tearing the nerve below the ganglion The same procedure was repeated on the other side extracting the sixth and seventh dorsal ganglia Not a drop of cerebrospinal fluid escaped the dura mater not being opened at all as each sheath had been closed by the ligature before it was cut Only three ganglia were resected as the patient was so debilitated and did not stand the chloroform well The wound healed promptly and the man has been free from gastric crises since but the preexisting lightning pains in the limbs and bladder symptoms still continue and the latter seem to have increased in intensity A zone of anesthesia on the right has developed corresponding to the ganglia excised Sicard and Desmarest think that the lesions in tabes are too diffuse to permit much operative relief, but that intercostal neuralgia might be arrested by this operation and that this is its most promising field Not long ago they performed a Franke operation to relieve the paroxysmal pain left from an intercostal zona No benefit was derived but they are convinced that this method of gangliectomy would have certainly cured their patient

71 *Eclampsia Result of Defective Elimination of Substances Produced to Nourish the Fetus (Eclampsia gravidarum und Paresis puerperalis) C Persson
72 Toxicity of Urine of Parturients (Verhalten der Harngiftigkeit in der Schwangerschaft in der Geburt und im Wochenbette mit Berücksichtigung der Eklampsie) P Esch
73 Pathologic Young Human Ovum (Ein junges pathologisches menschliches Ei) Todyo

65 **Dilatation of Kidney Pelvis**—Schickele says that roentgenoscopy of the kidney will frequently show that the pelvis and ureter may be distended without inflammation and that the pain is merely the result of accumulation of urine above some compressed point generally in pregnant women Treatment therefore need be only rest removal of the compression and copious drinking In case of infection injection of a local disinfectant is indicated The main point he emphasizes is that a gynecologic examination should always accompany roentgenoscopy of the kidney pelvis Ascending infection from the bladder is often due to some interference with the normal outward stream through the ureters although blood borne infection may be involved This is suggested by the rapid occurrence and rapid disappearance of the symptoms and by discovery of the germs in the uterus secretion blood and urine The colon bacilli may also find their way into the right kidney pelvis through the lymphatics, constipation favors this and if there is interference with the outflow of urine, pyelitis is almost certain to develop

68 **Thyroid Disease in Pregnant Women**—Rübsamen states that he found that 34 2 per cent of 718 women in the maternity at Berne had goiter, that is 246 while at Dresden during the same period one year there were only 0 29 per cent He discusses this material from various standpoints and also enlargement of the thyroid in the new born—In the nine cases of congenital goiter the mothers all had go In several cases temporary enlargement of the ge d in the newly born after difficult delivery

71 **Eclampsia**—Persson presents
sustain his theory that the ecla
peral paresis in cows are both d
retention of the substances which
ment of the fetus When the e
which has been passing thro
diverted to the breasts, and un

nourish the child find free outlet here, they accumulate and may have a poisonous action The resulting disturbances are liable to develop whenever there is a disproportion between the supply of nourishing substances for the fetus and the capacity of the fetus to use them or, after delivery, incomplete elimination of the substances through the mammary glands Treatment therefore should be to stimulate the production of milk and its outflow This he has done by milking the breasts, massaging them and applying suction hyperemia by Bier's method This is especially necessary in puerperal eclampsia The aim is merely to render easier the normal physiologic function of the maternal organism following delivery Anything that increases the viscosity of the blood should be strictly avoided, especially saline, while potassium iodid by rendering the blood more fluid has a very favorable action, so much so that he regards potassium iodid as almost a specific against eclampsia. He reports several cases in which headache, restlessness and other symptoms with pregnancy kidney warned of impending danger which he then warded off by potassium iodid His views explain the benefit derived from operations on the breasts in treatment of eclampsia, while they show that even better results are possible by merely stimulating the natural function

74 **Metastatic Cancers of the Skin.**—Askanazy reports a case which he thinks is unique the patient was a woman of 45, who six months after removal of a cancer of the breast developed numerous cancerous lumps in the skin involving nerve tissue Each time the patient was able to foretell the development of a lump by a peculiar sensation in the skin She located the pain exactly and within twenty four hours a new hard nodule had developed on the point about as large as a nut and not varying in size or consistency afterward The nodules were most numerous on the trunk and scalp and were identical in structure with the primary tumor

75 **Differentiation of Gastric Cancer**—Strauss gives the technical points useful for roentgenoscopic differentiation of ordinary gastric ulcer and a cancerous penetrating ulcer They both require operative treatment but the discovery of metastases in case of cancer may be a contra indication to an operation

77 **Phenolsulphonephthalein Test of Kidney Functioning**—Vogel joins in the chorus of commendation of Rowntree and Geraghty's method of estimating the functional capacity of the kidney (The technic was described in The Journal, Sept 2, 1911, p 811)

78 **Roentgenotherapy of Tuberculous Peritonitis**—Falk's experimental research has demonstrated that exposure to the Roentgen rays is a powerfully effectual adjuvant to operative treatment of peritoneal tuberculosis He is convinced that it would much enhance the benefit from a laparotomy in clinical cases

84 **Inoculation to Prevent and Cure Tuberculosis.**—Friedmann's communication, read at the Berlin Medical Society, November 6, was summarized in the Berlin Letter in The Journal, December 7, p 2081 Friedmann states that the remedy he is using is made from a strain of tubercle bacilli which have naturally very little virulence and which have been bred to practical avirulence for man It has been applied to date (November 18) in 1,182 cases of tuberculosis of all kinds, and a single intramuscular injection has been given as a prophylactic measure to 335 children from one hour to 3 years old In 90 per cent of the children a preceding skin tuberculin test had elicited a positive response. Many times the dose suitable for human beings was injected into guinea pigs without their showing the least ill effects or intolerance When killed years later they were found entirely healthy The avirulent bacilli had been totally absorbed and the animals were immunized thereby to a certain extent The immunization thus induced was unable to resist severe artificial infection, but the animals survived on an average 303 days while the untreated controls lived only 110 days The conditions of infection in man are never so menacing as in the artificial laboratory infection, and the outlook, he thinks, seems promising for permanent immunization by this means He states further that the continuous thriving to date of the inoculated children testifies to the harmlessness of the method He cited Bier, Schleich, Karfunkel and eighteen other physicians who have sent him tuberculous patients to be treated, and some of them regard the method as of great promise [In 1904 Friedmann published an account of his efforts to immunize animals against tuberculosis by inoculation with tubercle bacilli from cold blooded animals, supposedly avirulent for other species His "turtle bacilli" preparations were also applied in the clinic, but clinicians soon abandoned this treatment on account of the abscesses that developed at the point of injection An account of his work in this line was summarized in The Journal, 1904, xlii, 136, and xliii, 1909 Orth reviewed in *Virchows Archiv*, 1908, cxc, 1, the entire history to date of the method of treating tuberculosis by inoculation with supposedly avirulent tubercle bacilli In the discussion that followed Friedmann's communication, Karfunkel, Schleich and K. Küster reported surprising benefit in all their cases and a cure in many, while some of the others he had cited were much less enthusiastic Blaschko reported abscesses at the point of injection and the death of two patients Citron remarked that Friedmann had not yet entered into details in regard to his work but to date had announced only the general principles on which it is based He warned that as long as we are ignorant of means to control the virulence of bacteria, at any moment an avirulent virus may develop virulence in our hands and we be unable to prevent it He cited Pasteur's experience in this line, the vaccination against chicken cholera which at first had proved so successful and seemed so promising, suddenly started severe epidemics as, for some unknown reason, the previously avirulent virus had become virulent For these reasons, physicians have shrunk from applying this principle in therapeutics Citron added that while there may not be so much cause for concern in the treatment by this means of severe tuberculous processes, yet that there is every reason to refrain from inoculating clinically healthy individuals with a living virus when they merely display a positive reaction to the tuberculin skin test He urges greater caution for the future, at least until Friedmann has made it clear to the medical world what his inoculation material actually is In his previous research Friedmann announced that he was using tubercle bacilli from cold blooded animals—turtles—but he has not informed the world as yet whether his present remedy is from this source or not He describes it merely as a living avirulent bacteria material of tuberculous nature (*Bakterienmaterial tuberkulöser Art*) F Klemperer recapitulated the history of previous attempts to make a tuberculin for clinical use from bovine and turtle tubercle bacilli, stating that the turtle bacilli preparation had to

be dropped as its injection caused local suppuration at the point of injection Goldscheider expressed regret that the reports on treatment with Friedmann's remedy were not accompanied by exact details, the mere general impression of subsidence of night sweats, return of appetite, etc, are not sufficiently scientifically accurate to serve as the base for estimation of the condition before and after treatment He urged the society not to go on record as tacitly approving the inoculation with living bacilli of such large numbers of young children merely on the ground of a positive tuberculin skin reaction The discussion on Friedmann's communication at the Berliner med Gesellschaft was announced to continue at the next meeting]

98 *Impressions of America (Nach dem Washingtoner Kongress) A. Pröbsting

90 **Salt and Water in Dietetics**—Strauss states in the course of this general review of the importance of salt as a link in the chain of factors leading to dropsy, that abstention from salt benefits only when the retention of salt is due to parenchymatous nephritis When the dropsy is of cardiac origin, the intake of salt has no influence on it, nor on gastric secretion, that is, in his experience he was never able to bring about a normal secretion of gastric juice in cases of anacidity, even by the most copious intake of salt On the other hand, he has had cases in which large amounts of extremely acid stomach content were vomited repeatedly while the urine for weeks contained only traces of salt—a sign of the salt starvation of the body In some cases this salt starvation from incessant vomiting of the hydrochloric acid in the stomach, with extreme motor insufficiency, entailed severe prostration and spasmophilia, subsiding only when large amounts of physiologic salt solution were administered by subcutaneous or rectal injection The "salt fever" in young children is due more to the sodium *ion*, he thinks, than to the chlorin *ion* In heart disease, abstention from salt is useful only as the patients are less thirsty and thus are not tempted to drink so much It has been his impression that a tendency to uremia is more marked in nephritis without dropsy than in the dropsy cases the retained fluids dilute the retained poisons and thus are beneficial In diabetes insipidus, also, restriction of the salt intake is advantageous as it reduces the thirst and thus aids in combating the tendency to polyuria, and is useful also in polyuria from any cause and in the treatment of obesity He agrees with Bunge that people take too much salt as a rule, but the harm comes from the resulting thirst which leads them to drink beverages which are not always conducive to health

91 **Treatment of Arteriosclerosis.**—Strubell reiterates that in treatment of arteriosclerosis we cannot hope for more than slight improvement in a few of the symptoms but that this is often supremely *important* Chief of all is *the encouraging* influence of the physician, combating the depression and frequent tendency to suicide Strubell does not approve of too stringent restrictions, age brings so many of itself that the arteriosclerosis need not add many more The most important point is to ward off impending arteriosclerosis by hygienic living and diet, exercise, treatment of incipient tendency to kidney disease or gout, and avoidance of excesses of all kinds with special care to prevent congestion in the abdomen Plethora in the abdomen leads to overfunctioning of the vessels connected with the internal organs and thus brings undue strain on these vessels with resulting sclerosis He thinks that much can be done in this way to ward off arteriosclerosis which otherwise is invited by the hurry and stress of modern life Among the sedative measures he has found useful in arteriosclerosis are electric baths with the alternating current. Carbonated baths might be useful if the technic were perfected, but this is very faulty to date, he says, relating instances of direct harm from the carbonated baths now in vogue (The importance of diet in warding off impending arteriosclerosis was emphasized in a recent editorial, p 1976)

94 **Tuberculous Foci in Long Bones.**—Böcker reports three cases to sustain his view that on the least suspicion of involvement of the joint in a focus in a long bone near a joint operative measures are contra indicated as a rule He advocates the clearing out of the process only when the focus is certainly entirely outside of the capsule and there is no danger of infecting the joint if the focus is opened up His cases show that a sequester may become encapsulated and the focus heal without further disturbance The gait later in one such case was interfered with by a sequester as large as a cherry ensconced in the trochanter like the kernel of a nut, it had caused no trouble until after a fall on the hip The patient was a boy of 9 and the symptoms then were assumed to be a *flaring up again of an old healed process in the hip joint* When the sequester was shown by roentgenoscopy it lay so accessible that it was removed as a preliminary measure to the contemplated operation on the hip joint, but it proved to have been responsible for all the disturbance Its removal was followed by a *permanent disappearance of all symptoms* The nest of the sequester communicated with the joint, but its prompt removal after the trauma, before it had set up trouble *inside the joint, arrested all further disturbance* The cavity left by its removal soon grew up with bone tissue. In the second case the clinical tests seemed to indicate that there was no connection between the focus and the joint but the operation proved that there was and infection followed In a third case the suspicion of a connection deterred him from operating but *the process healed permanently under conservative measures* and time proved that the joint was intact. Whatever treatment is applied, he adds, potassium iodid is a valuable adjuvant Bier recently demonstrated this by three patients cured by stasis hyperemia and potassium iodid internally in an unusually short time and with none of the complications so often observed under prolonged hyperemia treatment

98 **Impressions of America.**—A rich crop of letters is sprouting every week in our exchanges written by members of the large party of physicians who toured the United States at the time of the recent International Hygiene Congress Pröbsting here states that people in Germany can form absolutely no conception of the public libraries in America or of the park systems in the large cities especially in Chicago Personal hygiene is more highly developed than in Germany, but public hygiene lags far behind He deplores that the rich in Germany do not seem to feel that *richesse oblige* as well as *noblesse oblige*, the fact that so many charitable institutions in America are endowed by private means being to him the most wonderful thing about the medical institutions he visited He adds that all the party found stimulation in the congress addresses and discussions and "the small exhibition" connected with it Germany has much yet to learn, he remarks, in regard to the hygiene of children He says of the Chicago stock yards that here the division of labor—specialization—is seen in its extremest development, man is merely a machine To the thinking observer it seemed actually a degradation of the Human

104. **Peptic Duodenal Ulcer.**—Gruber found peptic ulceration in 7.7 per cent. of 5,884 adult cadavers, 1.5 per cent. were in the duodenum, 6.7 per cent. in the stomach, 0.1 per cent. in the esophagus. He summarizes the clinical history of the 140 cases of peptic duodenal trouble; in 17 per cent. perforation was the cause of death. He calls attention anew to the connection of peptic ulcer with circulatory disturbances. In comparatively few of the cases had the duodenal ulcer been diagnosed during life. In 75 per cent. it had been overshadowed by some other affection. His experience shows that latent peptic ulcer occurs comparatively frequently in persons with arteriosclerosis, and may first manifest its presence by a severe open or prolonged occult hemorrhage. Especially in the elderly the possibility of this should not be forgotten.

105. **Operative Treatment of Sagging Stomach.**—Schlesinger gives an illustrated description of cases in which all internal measures had failed to relieve and he restored approximately normal conditions by cutting out the middle third of the stomach, uniting the stumps directly after this wedge-shaped resection, striving to have the stumps of about equal diameter.

107. **Operative Treatment of Pulmonary Processes.**—Külbs states that fourteen patients were cured of the twenty-four operated on for putrid abscesses of the lungs and three were much improved, seven died. He comments on the rapid subsidence of all symptoms after the operation and compares his experience with the 600 similar cases on record with a mortality of 17.5 per cent.

108. **Favorable Influence of Intercurrent Infectious Disease on Chronic Affections.**—Gerhardt reports six cases of this kind but the benefit was only transient in all. In the first a woman of 72 with intense trigeminal neuralgia had no pain in this region during the course of croupous pneumonia; pneumonia seemed also to abolish the pain of bilateral sciatica from a tumor in the sacrum in another case. In a third case of tuberculous ascites the diuresis became remarkable during an intercurrent pneumonia and the ascites disappeared for the time being. In the other cases the symptoms of pressure on the brain from a tumor ceased during an attack of measles, an acute psychosis subsided temporarily during erysipelas and a subchronic articular rheumatism caused no symptoms during an attack of follicular tonsillitis. In all the cases the pains kept off for a few days into convalescence; in none was the consciousness impaired. In connection with these experiences he mentions Bloch's recent report of a case in which a parasitic affection healed when another part of the body had been inoculated with another parasite (*Achorion quinckeanum*).

111. **Nephrectomy for Kidney Tuberculosis.**—Suter reports eighteen women cured by nephrectomy and ten men, with seven women and nineteen men materially improved. Five of the women passed through a pregnancy later. Only one of the five patients who have died since the nephrectomy succumbed to involvement of the lungs. The fact must not be forgotten that after the nephrectomy the patients are still tuberculous, and consequently that the general measures should not be omitted. He urges the general practitioner to pay special attention to the possibility of kidney tuberculosis in all obscure and spontaneous catarrhal affections of the bladder or kidney trouble. This is the only means to enable the recognition of the local tuberculous process in the kidney in the stage in which the entire disease focus can be removed. He cites two cases out of a wide experience in which the operation was refused, and although the kidney process apparently healed, yet complications developed in the other kidney or testicle with other serious features, confirming the dangers of leaving a tuberculous kidney in the body.

112. **Septic Rheumatoid Disease.**—Schürer found the *Streptococcus viridans* in three cases of what was apparently acute articular rheumatism, only that no benefit was derived from salicylic medication. He ascribes great importance to tonsillectomy in treatment of septic articular rheumatism.

115. **Treatment of Ankylosis of Joints.**—Wahl lays special stress on the prevention of ankylosis after phlegmonous processes involving the joints. He describes and illustrates a number of mechanical appliances which permit extension or rotation of the joints with other features to cure and prevent stiffness.

118. **Treatment of Furunculosis and Carbuncles.**—Schüle advises cauterizing the center of an incipient boil as the best measure for aborting it. He applies a little local anesthesia before the actual cautery. The first boil is generally too far advanced before it is seen but the following one treated by prompt cauterization in its early stage is aborted and the crop is thus destroyed.

Heddäus emphasizes anew the great value of a deep circular incision around a carbuncle down to the muscle or periosteum. This localizes the trouble and the result in his cases has been striking. He here relates a case in a diabetic in which the benefit was noticeable although the patient succumbed to the pre-existing complications.

119. **Prophylaxis of Epidemics.**—Göhring reports another instance of the way in which it is possible to nip a typhoid epidemic in the bud by search for bacillus carriers in the environment and training the carriers in the principles of prophylactic care. He also calls attention to the necessity for greater importance being paid to the negative findings on bacteriologic examination. In two recent cases the diagnosis of typhoid seemed certain except for the absence of typhoid bacilli from the stools and necropsy revealed miliary tuberculosis.

129 *Reform in Advertising Medicinal Articles. (Wünsche zur Reform des Arzneivertriebes.) W Heubner. (Von der Arzneimittelkommission des D. K. für Inn. Med.)

122. **Protection of the Peritoneum.**—Hoehne has been much pleased with the results of the injection of 30 c.c. of a 1 per cent. camphorated oil before operations to induce a local protecting reaction on the part of the peritoneum as a barrier against general infection in abdominal operations in which asepsis cannot be counted on. In his experience with 234 "unclean" abdominal operations, including 113 uterine cancer cases, there were only twenty deaths and for only two of these was a suppurative peritonitis responsible. In both of

these cases the connective tissue in the small pelvis was probably the source of the peritonitis after removal of the uterine cancer In the eighteen other fatal cases there was no peritonitis and necropsy revealed the desired reaction to the camphorated oil It permits the abdomen to be sutured, and in the 350 cases in which he has applied the ante operation oil treatment there was no sign of injury from it in any instance Recent reexamination of 150 patients showed the absence of adhesions or of any signs of ileus In case of much infection it might be wise to follow the operation with a second smaller injection of oil He has been applying the method for three and one half years and states that his experience is confirming more and more that the reaction localizes the infection and destroys the germs in the abdominal cavity by mobilizing the exudation forces, the strength of which depends on the capacity of the peritoneum for reaction the choice of the irritating substance and the duration of the irritation The protection is confined to the germs in the abdominal cavity and does not exclude infection from the soft parts He does not think that injections after the operation answer the purpose at all, as the reaction comes too late but it might prove a useful adjuvant

127 **Quackery and Nostrums**—Springfeld reviews the legislation on these subjects in Germany and the history of the measures that have been proposed against them, especially the agitation for a central standardizing office for new remedies He states that if the nostrum business could be eradicated millions would be saved to the people sufficient to finance all the wished for reforms to stamp out tuberculosis By checking the flood of quackery also more human lives would be saved than by the national social insurance

128 **Aspirin and Acetylsalicylic Acid**—Linke reports that those who have found that non proprietary brands of acetylsalicylic acid contain free salicylic acid, while the proprietary brand "aspirin" is free from it, obtained their results through the employment of faulty chemical methods Linke states that those interested in aspirin admit that, depending on the peculiarity of the patient, both 'aspirin" and acetylsalicylic acid produce gastric disturbances which disturbances are not uncommon according to Linke's own experiences As in acknowledgment of this it is reported that the Farbenfabriken are attempting to introduce a substitute for "aspirin which is said to be especially useful where aspirin is not well tolerated Linke has found acetylsalicylic acid von Heyden to be the equal of aspirin both chemically and therapeutically and concludes with the assertion that a good acetylsalicylic acid under the same conditions and with the same patient acts as promptly and efficiently as aspirin—which is a good grade of acetylsalicylic acid and nothing more—and that both in a given case produce equal gastric disturbances (See The Journal, Nov 2, 1912, p 1642

129 **Reform in Advertising Medicinal Articles**—The committee appointed by the German Congress for Internal Medicine—which is entitled to be called the German Council on Pharmacy and Chemistry—announces that it has recently elected six consulting members in addition to the six regular members The regular members are Penzoldt Gottlieb W Heubner, G Klemperer, A Schmidt and Spatz nearly all editors as well as internists The consulting members are W A Puckner as representative of the Council on Pharmacy and Chemistry of the American Medical Association Mannich of Gottingen, as representative of scientific pharmacy Dippe of Leipsic as representative of the German Aerztevereinsbund and Salzmann of Berlin, as representative of the German Apothekerverein O Heubner of Berlin as adviser in pediatric and Bettmann of Heidelberg in dermatologic matters In addition F Fischer Thoms and His are a special advising council The commission has installed its office at Nikolausberger Weg 23, Göttingen in charge of Dr O Loeb All questions and communications should be sent to this office The commission is soon to publish a second list to contain the approved articles The list B the previously negative list, will follow later In addition to the publication of these lists, the organized medical press has agreed to submit all advertisements to critical inspection before accepting them, so that a number of advertising abuses will be eliminated at once It is hoped by the committee that this self regulation inside the profession, will gradually lead to a reduction in the grossest abuses Further details in regard to what is practically the analogue in Germany of our own Council on Pharmacy and Chemistry are given in the current Berlin Letter December 7 p 2081

146 *Laceration of the Dura Mater of the Child During Delivery (Om Bristningen i Dura mater opstaaede hos nyfødte under Fødslen) L Meyer and E Hauch

146 **Laceration of the Dura Mater During Birth**—Meyer and Hauch have made a special study of this subject since Benecke recently called attention to the importance of laceration of the tentorium in the pathology of the new born In order to study this laceration the skull has to be opened with special precautions, as they show with several illustrations Examination of the skulls of sixty four infants born dead or dying soon after birth at the Copenhagen maternity, showed rupture of the dura in twenty eight cases The laceration was the cause of death in only twelve of the cases, the proportion was thus 1 per cent in the total 1,200 deliveries during the six months with sixty four of the children stillborn or dying soon after birth The tentorium is very rich in blood vessels and the outcome depends on the extent of the laceration and size of the vessel involved

In thirteen of the children the rupture was probably the cause of death, including six stillborn, one delivered in breech presentation and five in vertex presentation all difficult forceps cases In fifteen of the cases the laceration was without clinical significance In the seven children who were born alive with serious rupture four died almost at once, one was born spontaneously in vertex presentation four weeks before term and both tentorium and falx were completely torn with great hemorrhage Another of the children in this group was syphilitic and there was partial laceration on both sides One child was born a month before term and the longitudinal sinus was found ruptured with great hemorrhage The findings in each of the cases of fatal laceration of the dura are illustrated and the details tabulated They demonstrate that the rupture occurs during spontaneous delivery only in small, prematurely born children or macerated fetuses or fetuses which have died just before birth When rupture occurs in a well developed child there has always been some preceding difficult obstetric *manipulation or the rupture is of insignificant extent* The head of a prematurely born child may not be able to stand the strain of even a spontaneous delivery In a recent case a child was being delivered by cesarean section and just as the chin and mouth were passing through the opening in the uterus a violent contraction occurred, compressing the head for a few seconds, but releasing it again at once The child was small (2 150 gm), but at term It died ten hours later and the *tentorium was found torn on both sides* with considerable hemorrhage During the period in question forceps were applied in sixty six cases but this was a simple matter in all but twenty In this latter group the forceps got a good hold in twelve cases and no lacerations occurred, while in the eight cases in which the application of the forceps met with some difficulty there was rupture in every instance Pressure on the head from the front backward seems to be the most dangerous in this respect The falx is not so rich in vessels as the tentorium and consequently laceration here is less serious (A previous communication on this subject was summarized in The Journal, June 15, 1912, p 1888)

149 *Nervous Disturbances from Cervical Ribs (Nervelidelser som Folge af Halsribben) K H Krabbe

149 **Nervous Disturbances from Cervical Ribs**—Krabbe reports six cases which emphasize anew the variability and severity of the clinical disturbances that may be induced by supernumerary ribs in the neck In two cases the functioning of the arm was interfered with and there was pronounced scoliosis, the latter is a frequent finding with cervical ribs Another patient was a man whose left arm and leg had always shown some atrophy At the age of 30 the left arm developed gangrene, compelling amputation before the cervical ribs—the cause of the vascular disturbance—had been discovered The symptoms suggested syringomyelia in some respects In the other cases the trouble was in the peripheral nerves, in one case the course was so acute and painless that poliomyelitis was suggested while in the others the trouble came on gradually and the pain became so intense that life was unbearable The diagnosis in one case had been a spinal tumor, roentgenoscopy was negative and no benefit was derived from drugs and electricity After seven months of various measures, the patient, a girl of 22, was presented at a meeting of neurologists and the diagnosis discussed, some inclining to accept a spinal tumor, others syringomyelia others Klumpke's neuritis or a neuritis with functional disturbances The first sign of trouble had been noticed at the age of 12 but the pains did not develop until five years later The possibility of cervical ribs was mentioned but discarded owing to the negative Roentgen ray findings On assumption of syringomyelia, roentgenotherapy was applied but proved futile as also all medication After six months of agonizing pain the patient insisted on an operation of some kind and roentgenoscopy then with special regard to the neck revealed the cervical ribs and prompt recovery followed the operation for their removal One lesson taught by the martyrdom of this patient is that roentgenologists seldom *think of the possibility of cervical ribs* in this case the anomaly was at the seventh cervical vertebra the rib being 3 cm long, too small to be palpated and not evident on roentgenoscopy until specially sought for A special feature of the case is that a sister of this patient also had cervical ribs causing trouble and three brothers had a slight tendency thereto while the seven other children in the family were free from it Krabbe's six patients were between 16 and 34 and the cervical ribs had caused no disturbances until from one to ten years previous.

PULMONARY TUBERCULOSIS AS AN OBSTETRIC COMPLICATION *

CHARLES S BACON, MD
CHICAGO

To obtain an approximate idea of the frequency of tuberculosis during pregnancy we assume in the absence of data that it is about the same as among women of the child-bearing age From 25 to 29 per cent of all women in this age period die of tuberculosis and the general death-rate for the period is 8 per thousand Consequently the yearly death-rate from tuberculosis for women between the ages of 15 and 50 is from 2 to 2 3 per thousand Now, assuming an average duration of the disease of from five to eight years this would give a frequency between 1 and 2 per cent This would indicate that every year there are in the United States between 22,000 and 44,000 gravidæ with active tuberculosis in one of the three stages

Probably if all latent cases were included the number would be greater I omit consideration of such cases that do not become active during pregnancy Until there is more uniformity in methods of diagnosis and classification it is impossible to secure data from different clinics and institutions which can be used in computing the extent of the disease The adoption of the suggestion of Flick of Philadelphia, made at the recent International Congress on Tuberculosis in Rome, would help to secure more reliable data He proposes a standardization of the symptoms of tuberculosis and the adoption of an international history sheet The introduction of such a uniform system of examination and records would bring uniformity into the statistics which now show a variation of from 1 to 50 per cent in the frequency of tuberculosis in different institutions

The management of this complication depends on the effect of tuberculosis on the egg and on the pregnancy, and also on the effect of pregnancy, labor and the puerperium on the course of the tuberculosis Considering first, the effect of tuberculosis on the fetus, it must be admitted that fertilization and nidation may occur in a tuberculous tube or uterus This eventuality is, however very rare, but the infection of the decidua, placenta and chorion has been shown by a number of observations to occur not infrequently When this happens, the blood of the fetus may contain tubercle bacilli Only further observation can determine how often this occurs Also infection through the spermatic fluid may occur

The discovery of tuberculosis in the first two months of child life, however, is rare Practically all observers agree that tuberculosis when it is found in infants is the result of infection after birth It may be that fetal infection is easily overcome during intra-uterine life A marked immunity at birth, however, does not exist Some predisposition to the disease may occur The nature of this has been much discussed, but without result

EFFECT ON PREGNANCY

The effect of tuberculosis on the course of pregnancy is slight In some cases in which there is considerable involvement of the placenta or decidua, abortion may occur

The effect of pregnancy on the course of the tuberculosis differs much in individual cases, depending on the progress of the disease, the surroundings of the patient and the existence of complications, such as foreign infections and toxemias If the patient gets through the first three months well there is often an improvement in her condition She may increase in weight and in strength and come to labor in fair condition This favorable course is more common in tuberculosis in the first stage Sometimes it is found in the second stage of the disease In both the first and the second stages the patient may begin to fail in the last three months Respiration becomes difficult, coughing is very disturbing, the woman becomes very weak and loses weight In the third stage the prognosis is always bad and the woman may die before labor begins

The description just given is not agreed to by all Many contend that there is always an increase in the tuberculous process during pregnancy Assuming this to be a fact, various explanations have been given to account for it A pregnant woman is not particularly susceptible to other infections The special susceptibility to tuberculosis of the lungs has been attributed to the contraction of the thorax and disturbance of respiration by the lifting of the diaphragm and venous congestion Also to the tissue changes in the lungs and air passages have been ascribed deleterious influences

To these factors which indirectly favor the development of the tuberculosis, have been added others which might directly favor the growth or increased virulence of the tubercle bacillus Among such alleged factors are changes in the number and character of the leukocytes and also of the opsonins of the blood of pregnant women Recently Hofbauer has held that there is a decrease in the lypolitic enzymes of the blood serum of pregnant women which leads to a lipemia that favors the growth of the tubercle bacilli This theory not having been confirmed more recently still he and Christofoletti and Thaler have tried to show that there is a condition of lipoid anemia — cholesteremia — that is favorable to the development of [illegible] rculosis germs This latter theory remains [illegible] or disproved Meantime we cannot adm[illegible] cl[illegible] h these workers have tried to explain, viz, that all such cases grow worse during pregnancy

---

* Read in the Section on Obstetrics and Gynecology of the American Medical Association at its Sixty Third Annual Session held at Atlantic City June 1912

If the patient has passed through pregnancy in good condition, labor may be quite normal, especially when there are no pathologic conditions in the passages or passenger If she be very weak labor may be a serious strain

It is acknowledged that in the puerperium the tuberculosis generally becomes worse even in milder cases, and in bad cases the patient may succumb within a few days or a few weeks Perhaps the strain of labor breaks up old infection foci or causes injuries which complicate the situation One is reminded of the exacerbation of appendicitis in the puerperium

PROPHYLAXIS

There are two problems in prophylaxis, the prevention of pregnancy in a tuberculous woman and the prevention of infection in a pregnant woman or one liable to become pregnant The latter problem is very important and often overlooked or slighted

The chief danger of infection for the woman is from her husband A man with tuberculosis should not marry If a husband acquires tuberculosis after marriage, he should avoid infecting his wife Every consideration of reason and affection demands this course It is the duty of all who are interested in preventive medicine, not only health officers, but also the medical profession, to spread information on this subject There is nearly as much reason why a tuberculous man should not marry as why a tuberculous girl should not marry If in the married life, the husband acquires tuberculosis first, i e, before his wife, he should, if possible, undertake a sanatorium cure Even if a cure is not accomplished, he learns in the institution how to avoid infecting others and acquires the intelligent self-control necessary to the avoidance of the greatest danger

The other problem in prophylaxis is the prevention of pregnancy in a tuberculous woman Of course a girl with active tuberculosis should not marry This should be taught in all possible ways until it becomes a moral law in every civilized community The prevention of pregnancy in a tuberculous wife can be accomplished by abstinence from sexual congress by the use of measures to prevent conception and by artificial sterilization

Of course, we advise abstinence Sometimes it will be practiced, but rarely can we feel certain that it will be continued for any considerable length of time Preventive measures are generally failures in the end Hence we come to the somewhat complicated question of artificial sterilization

ARTIFICIAL STERILIZATION

It is not immoral in itself The serious objections to the induction of abortion do not apply to it The chief objection is that the patient may recover from the infection and then desire to have a child This objection is overcome by doing a temporary sterilization For nullipare or women with only one child or women who have a good chance to recover a temporary sterilization should be chosen For women who already have several children or those who have very little prospect of a permanent cure some permanent sterilization operation may at times be preferred

Whatever operation is made it is especially important that a written agreement be had with both wife and husband in order to avoid future possible legal complications

It is well known that a simple ligation of the tubes is not a reliable method of producing sterilization Neither is the incision between double ligatures sufficient It is necessary to bring the uterine end of the tubes under the peritoneum or within the broad ligament This can be done through a vaginal celiotomy and is among the simplest and safest of gynecologic operations in the absence of pregnancy, and with a patient in a fair condition Later it will be possible, if the patient recovers from her tuberculosis, to implant the distal part of the tube into the uterine portion

Several reasons may favor combining the sterilizing operation with the induction of therapeutic abortion This may be done if the pregnancy has not advanced beyond the tenth or twelfth week Schauta favors the practice and avoids injury to the large, soft and congested uterus by catching the round ligaments one at a time and bringing the isthmial portion of the tubes into the peritoneal opening After the twelfth week of pregnancy it is better to empty the uterus if abortion is necessary and to wait a few weeks before sterilizing

The two most important methods of permanent sterilization are castration and hysterectomy Bumm combines them He and others contend that removal of the ovaries will favor the healing of the tuberculosis through its tendency to cause an increase in the fat which helps the struggle against the infection Others deny that the healing of the tuberculous process is effected by such an increase of fat in the body and hold that the nervous and psychic disturbances arising from the removal of the sexual glands is an injury to the patient

Castration may sometimes be indicated as a sterilizing operation in order to stop the menstruation that may be attended with much pain or with serious loss of blood Hysterectomy would meet the same indications and alone might be preferable to castration as the organism would retain the ovarian glands whose secretion might be of value for some time The combination of the two procedures in the Bumm operation seems contrary to conservative practice and can be justified only by exceptional clinical results

Pincus' method of atmocausis or obliterating the uterine cavity by burning it out with superheated steam has not found much general favor The use of the Roentgen ray to destroy, more or less completely the sexual glands is too uncertain to promise much for the future

When both husband and wife are tuberculous, it would seem more reasonable to sterilize the husband by an operation on the vas deferens This would be equally efficient and less dangerous, as it is generally made without an anesthetic

INTERRUPTION OF PREGNANCY

If in spite of advice and care a tuberculous woman becomes pregnant or if a gravida becomes infected with tuberculosis, the first question in the management will be that of the interruption of pregnancy There are two indications for the induction of abortion in this condition first, the vital indication, when it is necessary to save the life of the gravida who is in immediate danger of dying, and second, the prophylactic indication, when it is done to prevent the development of the disease which may be expected to occur from gestation and labor The operation is rarely done for the vital indication It does not hold with a patient in the first stage of tuberculosis and with one in the second and third stages only in the last half of pregnancy when artificial abortion is generally useless

Practically, nearly all therapeutic abortions for this complication are made for the prophylactic indication The justification of the operation depends on the correctness of the assumption that the patient's condition will suffer serious injury by the continuation of gestation and that this injury can be averted by the abortion It is evidently very difficult to reach objective certainty with such an assumption The correctness of the conclusions must depend on the ability of the physician to form a correct judgment Assuming that he possesses a good theoretical knowledge of the premises and an acute sense of his responsibility, yet he must have experience Few physicians have seen enough cases to enable them to form a correct judgment from their own experience The reports from the literature are hardly encouraging Veit collected 745 cases of induced abortion for this complication Of this number the outcome was given in only 347 cases In only 199 or about 57 per cent were the patients reported as improved One patient died as the result of the operation and 107 patients died within a short period while forty-one more are reported as unchanged This shows an absolute failure of the operation in about 43 per cent of the cases This is certainly a discouraging outlook It may be admitted that not all of these operations were done from the prophylactic indication Also, there is no classification of the cases showing the stage of the disease The report is valuable, however, to counteract the impression that the justification of the operation may be assumed

It is indeed possible that more years of life would be saved if the operation were entirely abandoned We have of course the destruction of fetal life or a fetal mortality of 100 per cent Is this offset by the increased length of life of the 57 per cent of mothers whose condition is improved by the operation?

The legal aspect of the question demands attention Our laws do not recognize the prophylactic indication Only those abortions are exempted from the penalties of the criminal act that are done to save the life of the mother It is generally assumed by physicians that an abortion done to save the health of the mother would also be accepted, but lawyers by no means agree to this assumption In Germany this feature of the law has been much discussed in the last two years

It is certainly not easy to find a logical justification of the prophylactic abortion It is, of course, feticide — a destruction of human life Who has the right to destroy this life? Has the mother? If so, can she give the right to a third person? When the mother is in imminent danger of death from the fetus it may be admitted that she can protect herself by destroying the fetal parasite But when there is only an assumption that her health may be injured by the presence of the fetus, her right to take the fetal life is certainly much more questionable

These considerations simply show that the question is a complicated and serious one, and that the responsibility of the physician who decides in favor of the measure is great It is certainly desirable that the decision should be made only after a professional consultation It is often true, however, that an internist is more apt to recommend the operation than to veto it The obstetrician is not freed from his responsibility when an operation is recommended that he cannot approve It would be no less than degrading for anyone to employ his skill as an instrument to do what he considers wrong or unjustifiable

My own conclusion is that we must individualize Sometimes, but rarely, abortion is justified It should be done in the second half of pregnancy, only for the vital indication All effort here should be made to save the fetus — to bring it to a safe viability term If that cannot be done and the mother is about to die, we may take the only chance to prolong her life In the first half of pregnancy we should carefully watch the progress of the disease If the patient is under the most approved treatment and nevertheless grows worse, as shown by cough, fever, and loss of weight, with hemoptysis, then abortion should be induced We must particularly take into consideration and allow for nausea and vomiting and other disturbances occurring in the second and third months of pregnancy On this account it is sometimes difficult to decide on the operation before the fifteenth or sixteenth week

A study of the conjunctival and cutaneous reactions in tuberculosis have shown that in an advanced stage of tuberculosis there may be a negative reaction to either This is regarded as a bad sign since it denotes the lack of reaction in the organism Wolff-Eisner has proposed to apply this fact in confirming the indication for induction of abortion when pregnancy is complicated with tuberculosis In a case in which previously a positive Wolff-Eisner test showed a good reaction, its loss would denote a bad prognosis If the reliability of this test is confirmed it may assist in deciding on an operation

Much has been said of the social indication It is a dangerous subject but cannot be ignored A poor woman who has a number of children, who contracts tuberculosis and then becomes pregnant, is certainly in a different class from a well-to do young woman in her first or second pregnancy Without subscribing to the justifiability of the social indication as such, we agree that the social condition has a bearing on the prognosis and becomes a factor in deciding the prophylactic indication

It may not be out of place in this connection to add that abortionists are beginning to use the prophylactic indication as an excuse for inducing abortion in cases in which there is no suspicion of tuberculosis Women who wish to have an abortion have learned to use this plea and represent to the physician that they fear tuberculosis and desire help for this reason Criminal abortion is rapidly coming to be recognized as a crime that affects the morals, health and lives of a considerable portion of many communities and even seriously threatens the existence of nations Anything that encourages the crime must be avoided The induction of abortion for weak or doubtful indications must not be allowed

METHOD OF INDUCTION OF ABORTION

The best operation is one that involves the least risk from hemorrhage, infection and shock During the first twelve weeks the uterus may be emptied under anesthesia with rapid dilatation and curettage From the twelfth to the twentieth week a preliminary dilatation of from sixteen to twenty-four hours with laminaria tents should be employed Sometimes the tent dilatation is desirable as early as the tenth week whenever the cervix seems firm and might dilate with difficulty Of course, the danger of the curet must be kept in mind and only an instrument with a broad loop and a flexible shank should be used Some expert operators prefer a hysterotomy, but I believe the average physician will [illegible]e less risk with dilatation and curet [illegible] ha [illegible] ious stated, sterilization may [illegible] tion of the uterus In the rare cases of induction of abortion between the twentieth and twenty-eighth weeks hysterotomy is probably the safest and least exhausting procedure

During pregnancy the patient should be treated like any other patient with tuberculosis She should breathe fresh air, be well fed with good nutritious food and avoid exhaustion or fatigue Like other patients she must learn to take care of herself, avoid other infections and diminish the danger of infecting others Whenever possible a course at a sanatorium is desirable

During the entire pregnancy she should be kept under very close watch Temperature and pulse should be taken two or three times a day Weight should be taken twice a week Elimination by bowels and kidney should be watched The amount of exercise should be regulated and the amount of sleep attained should be known In particular the diet should be controlled and its exact caloric value determined and recorded

Even when the patient has done very well during the middle of pregnancy, she may retrograde in the last two months and reach a serious condition bordering on collapse on account of disturbances in nutrition and respiration Here the induction of premature labor is urgently indicated By relieving the patient from the most trying four to six weeks of pregnancy she comes to the arduous period of the puerperium in a better condition and with better prospects On account of the child the operation should be postponed to the end of the thirty-sixth week if possible Then it should be done so as to furnish the quickest relief Generally metreurysis after rupture of the membranes is the best method After the introduction of the bag pituitary extract may hasten the labor Sometimes a vaginal cesarean section will prove the most serviceable operation

The watchful care of pregnancy is redoubled during labor The physician should remain with the patient, not for the purpose of interfering but to observe the progress and the effect of the labor Every possible care should be taken to prevent infection In particular the third stage should be managed with patience to avoid hemorrhage and infection

It is a well-recognized fact that the puerperium is the period of greatest danger This may be due, as already suggested, to breaking up of old infective foci by labor and the lighting up of new and extensive infections in the lungs It may be due to the dissemination of tuberculous infection from the placenta Sometimes acute miliary tuberculosis occurs and is differentiated with difficulty from puerperal sepsis Genital wound infection may occur and become unusually virulent on account of the diminished resistance of the patient Loss of sleep from disturbance of the baby and from lactational troubles may be a factor If the patient has been used to sleeping in the open air and is now kept in a room, this confinement will distress her An unnecessary restriction of the diet may help to reduce her strength

All these disturbing factors should be considered in the management Granted a safe labor and subsequent care that obviates puerperal infection, with a good diet, fresh air, and removal of worry on account of the child, a tuberculous patient will avoid most of the dangers of the dreaded puerperium

NURSING IN TUBERCULOSIS

The objections to the nursing of the baby by the mother are the danger of infecting the child and the strain of nursing on the mother The child's chances of escaping infection are no doubt better if it is removed from the mother entirely However, this is often impossible The chance of infecting the child will be lessened if she has learned to take care of the sputum In poorer houses it is of great importance to train the mother If a mother has fever, cough and many bacilli in the sputum she should not be in contact with her child or with other members of the family In the first stage, however, the danger of infecting the child from nursing is not much greater than that which arises from caring for the child

That nursing is an added strain on the mother is true and this furnishes a good reason in many cases for forbidding nursing from the start or after a short time Consequently, the same care that was given to the gravida must be extended to the puerpera If she loses weight and begins to decline in strength, she must wean the child at once

The rule of procedure is as follows In any case, if the mother can afford to employ a wet-nurse she should do so If one is not to be obtained and the child is strong it is fed on modified cow's milk A competent child's nurse should take entire charge of the child If the child is weak or premature and not likely to thrive on artificial food it may nurse from the mother at least in part but with every precaution to prevent infection It is better to give the milk pumped from the breasts If the mother cannot afford to employ a wet-nurse or a child's nurse but must care for the child herself, she may begin to feed it once or twice a day Little by little she should wean it so that by the end of three or four months nursing is entirely abandoned The entire management must be strictly superintended by the physician

SANATORIUM AND DISPENSARY CARE

Municipal and private sanatoriums and dispensaries should give special care to women before confinement and to the mother and child At present there seems to be no provision for this class of patients in the United States Large institutions should have special departments for these cases In populous cities special sanatoriums for tuberculous gravidæ and for tuberculous children would be desirable To such institutions could be sent all patients who cannot be satisfactorily treated at home No other class of tuberculous patients is in as much need of proper treatment and no other class is at present so much neglected There are probably 10,000 women yearly in this country who should be sent to sanatoriums With an average residence of three months to each patient they would require 2,500 beds or fifty institutions with fifty beds each

A children's department should be provided in connection with the maternity department where children under 4 years, as a rule already infected, whom the mothers could not leave at home, might be received The establishment of free maternity and children's sanatoriums for tuberculous patients would attack the disease at its source and thus aid materially in its eradication

IMPORTANCE OF THE PROBLEM

In the study of this problem there is some danger that we lose ourselves in the discussion of professional technical details What is the end of the whole matter? It cannot be to save a few months or years of life to poor sick women who as long as they live will be sources of danger to their families and to the community It cannot be to bring into the world weak, defective children who become infected early and go through a short, miserable life spreading disease and undoing the work that has cost much effort and money It were better to sacrifice both women and children

Our aim is to save and cure tuberculous women if possible, if not, to prevent them from injuring others We must protect the children from infection This cannot be done by individual effort Concerted professional and social effort is necessary This is not simply a medical or obstetrical question in the old sense It is a part, and a very important part, of the whole tuberculosis problem

Seen from the point of view of public health and preventive medicine, the problem has a different aspect from that which it formerly presented to the short-sighted practitioner traveling in the rut of custom Prevention of pregnancy, whether it involves celibacy or sterilization, comes to be almost a moral law Induction of abortion remains the area still covered with the mists of doubt. Ethical, legal and professional mists make a uniform treatment impossible The care of the mother and the protection of the child demand professional, philanthropic and state cooperation and that alone promises great results

2156 Sedgwick Street

ABSTRACT OF DISCUSSION

Dr C. L Minor, Asheville I am in accord with the statement that the woman with active and progressive tuberculosis, producing constitutional symptoms, is unfit for marriage and unfit for the production of a child, but with regard to the woman whom we know perfectly well to be tuberculous, but who has no active trouble at the time, I think the rule that Dr Bacon lays down is too wide I have been called on very often to study the question in my patients, and I am not ashamed to say that I have allowed the marriage of tuberculous girls and I have seen a good psychologic effect and benefit to the patients from these marriages If the whole purpose of medicine is eugenics, possibly that may be wrong It comes down to a question of prognosis and in the estimate of prognosis, I imagine that the man who concerns himself with tuberculosis is better qualified to draw a conclusion than the gynecologist Granted that the actively tuberculous woman has had a child, what shall we do with the child? The veterinarian tells us that calves born of tuberculous mothers that are taken away at once and kept elsewhere grow up into healthy cows Hard as it is, the child of a tuberculous mother should likewise be separated from its mother, perhaps not absolutely, but the care must be extreme the separation as close to absolute as it is possible to make it This should be from the very beginning, except for one or two days There should be no nursing at all There is nothing more disastrous to a tuberculous woman than lactation In the eighteenth century and in the beginning of the nineteenth it was stated that pregnancy had a good effect on tuberculosis Since 1843 it has been recognized that this was a mistake and that it is disastrous, and yet, in the early months I have seen distinctly good effects Metabolism seems to be improved and things go splendidly After that point the course is usually downward If the tuberculosis is active I believe the abortion should be brought about in the early months From the fifth month on the consensus of opinion is, for reasons that have not been explained that interference has a worse effect than allowing the case to go to labor Instrumental interference favors dissemination If the patient goes to labor, Dr Brown of Saranac Lake has advised the use of chloroform to avoid difficult labor and exertion on the part of the patient and to prevent dissemination Lessening the loss of blood in labor is also very important. Active tuberculosis cases in which the process is making advances, as shown by constitutional symptoms, will in a very large majority of cases go down hill It has been said that the tuberculous woman may have one child with safety, two possibly, three never That, I believe, is true

Dr S M Brickner, New York What is it in the nature of pregnancy which when combined with an active tuberculosis makes for injury to the patient? Is it the increased strain for the support of the woman and infant? Is it the increase in toxemia due to the tuberculosis? Trembley of Saranac Lake has had a larger experience in the observation of pregnant women with tuberculosis than any one else in the world He has found that about 46 per cent of his tuberculous women who have become pregnant have died, although he has not stated the time each lived after conception, and 60 per cent of these pregnant women permitted to go through have died This would seem to offer an opportunity for the induction of abortion I would tabulate into three groups patients with active tuberculosis that have become pregnant 1 There are some in whom no therapeutic measure will offer any relief That would include those with laryngeal tuberculosis and miliary tuberculosis—women who would be certain to die under all circumstances 2 A group of patients might possibly be helped by an interruption of the pregnancy—those patients with a moderate infection only, not necessarily incipient, a little beyond the incipient stage, and yet who might by nursing and care and by having an abortion induced, be benefited as to their tuberculosis 3 There are unquestionably patients, and I have had nine under my observation, who with a moderate tuberculosis can safely be permitted to go through their pregnancy After all, as has been pointed out by Drs Minor and Bacon, the question is one of prognosis and I never would interfere with a woman who was actively tuberculous and at the same time pregnant, without the authoritative statement of an internist or one who specializes in tuberculosis, as to the possible outcome Even then it may not be possible to prognosticate which woman will go through with safety and which will not I was glad that Dr Bacon touched on the question of sterilization

Dr. R. L Dickinson, Brooklyn I have recently had occasion to review the German literature on the effect of the *x* ray on the ovaries Much work is being done by the best men and it is the general consensus of opinion that the *x* ray is of value in this direction It can be made to shrink an ovary and put it temporarily out of function by a few treatments In experiments on guinea pigs the ovary was reduced to one half the normal size, while the other remained full size As with the male operator in that line, the sterility is temporary Further experimentation with dosage and duration may demonstrate that sterilization may be effectively produced by non operative measures There is no measure for the woman so simple, however, as vasectomy in the male There is possibly a method which can be developed to be nearly as simple and quite as effective I have introduced a sound with a little platinum tip and produced a cauterization by heat at each corner of the uterus in order to produce a stricture and an obliteration I have not yet dared to do that on the living woman in order to sterilize, but have done it a few weeks before hysterectomy and have seen that the stricture occurs I shall sometime in the future show some of these cases and present the method for adoption As a rule, laparotomy is a very large contract to take just for the purpose of sterilization

Dr Henry Farnum Stoll, Hartford, Conn It is a good rule that the woman who has had active tuberculosis should not become pregnant until two years after the subsidence of all symptoms The symptoms are the important things, not the physical signs The straining during the second stage should be avoided by the use of forceps When the forceps has not been used there have been signs of recent extensive dissemination found at autopsy probably the result of rupture of caseous glands due to the terrific strain that takes place when labor follows its normal course When there is anxiety to have a child good results have been obtained by the use of tuberculin throughout pregnancy when given by men experienced in its use

In regard to the time of operation if the woman has the signs and symptoms of an active tuberculosis the abortion should be done early, [illegible]n the first few months, there is a high p[illegible] f[illegible] some stat[illegible] believe, being as high [illegible] ter, t[illegible]is less, and in the third stage, much less If the pregnancy is allowed to go on until after the middle period, very little can be hoped for as far as the mother is concerned from interrupting the pregnancy In general, it is better to terminate the pregnancy early than to try to get a living child In regard to a tuberculous mother nursing the child, the French Society for the Prevention of Tuberculosis reports 250 children removed from tuberculous mothers and in no instance did tuberculosis develop

Dr J C Litzenberg Minneapolis Two years ago in the Schauta clinic there were twenty two abortions in the women entering the clinic in five months Von Rosthorn was also of the opinion that certain women with active tuberculosis should have the uterus emptied One woman came in for the sixth therapeutic abortion Only then was she sterilized This opinion was also shared by the men in the medical clinic We sometimes form opinions and do things when we really do not have the statistics to back them up Unless they have changed their opinion in two years the clinicians in Vienna believe that every woman with active tuberculosis should in early pregnancy have the uterus emptied There is an exception made in those far advanced There is another condition in which operation is done if seen early—those with tuberculosis of the larynx, of whom 100 per cent die if the pregnancy is allowed to continue

Dr L M Gates, Scranton, Pa I do not believe that you can cauterize and be sure that you are doing any thing more than producing a stricture, and you are thereby liable to produce the worse condition of ectopic pregnancy I would also repudiate the use of chloroform in these cases as being an irritant to the lungs and an injury to the blood We all know that the use of chloroform increases the amount of blood lost by the patient The tendency with tuberculous women is to be relaxed and chloroform is a further relaxant When labor is over the effect of the chloroform is to cause post partum hemorrhage I would not use chloroform in the termination of labor with forceps in these cases

Dr T M Burns, Denver It seems to be true that a certain proportion of patients get worse, not because of the pregnancy, but because of the disease Another proportion get worse because of the pregnancy Another proportion stay quiescent and another proportion get better From my experience in Colorado I do not believe that the internist is capable of saying when we should produce abortion I know of several cases in which an internist said abortion should be induced but in which the patient went on to labor and was better than before pregnancy When the patient comes to us in pregnancy, I believe the better way is to watch her and as soon as she starts to get worse induce premature labor or abortion by means of two catheters or two bougies in the uterus and gauze tampon or a rubber bag in the vagina I do not believe this will produce any shock unless an anesthetic is necessary In many curettements morphin will take the place of ether or chloroform

Dr H G Wetherill, Denver I have not practiced sterilization, but it seems to me in view of the very great simplicity of sterilizing the male by vasectomy that the time has come when this simple operation should be considered to prevent pregnancy under these circumstances rather than an abdominal operation on the woman

Dr C S Bacon, Chicago Whether a woman is cured of tuberculosis and whether or not she dare marry are questions which we must leave to the specialist for determination I think the suggestion of Dr Stoll that two years' freedom from the disease is desirable is a good one The rule given by Martin of one year's freedom from the disease is generally adopted and I had that in mind I think two years would be still better I cannot understand how one can advocate inducing abortion on the same patient time after time for this condition If we are obliged in any particular case because of the special indications to induce abortion we should afterward insist on sterilization Nothing seems to me more harmful from all sides than a repeated induction of abortion As to the method of sterilization, of course these instruments of Dr Dickinson are interesting but we cannot rely on them at present We must have absolutely reliable methods Those who have spoken have assumed an abdominal laparotomy for tubal sterilization We can do a vaginal celiotomy with much less shock Some anesthesia may be desirable The ether anesthesia, as little as we can get along with, is much safer than chloroform The use of forceps is of course, not to be recommended in all cases A symphyseotomy may be done Under no circumstances should a dangerous forceps operation be undertaken The same obstetric principles as apply in all cases are to be observed

---

INTRADURAL ROOT ANASTOMOSIS FOR THE RELIEF OF PARALYSIS OF THE BLADDER

AND THE APPLICATION OF THE SAME METHOD IN OTHER PARALYTIC AFFECTIONS *

CHARLES H FRAZIER, M D
Professor of Clinical Surgery in the University of Pennsylvania
AND
CHARLES K MILLS, M D
Professor of Neurology in the University of Pennsylvania
PHILADELPHIA

Any method of surgical treatment which promises relief or cure of a distressing condition hitherto irremediable by any known treatment, medical or surgical, is worthy of close attention and of adoption after its value has been demonstrated Incontinence of urine and of feces, especially the former, in cases of traumatism causing complete or partial paraplegia is always a distressing condition, and not infrequently one of danger through the probabilities of cystitis and general infection

We believe that the following case is the first in which the operation of intradural anastomosis of spinal nerve roots (the first lumbar to the third and fourth sacral) has been successfully accomplished, and in only one instance has it, so far as we know, hitherto been tried The case, as the history will show, was one of severe traumatism at first causing complete paraplegia, including incontinence of urine and feces In a few months the paraplegia and accompanying anesthesia were largely recovered from, but the patient was left with an absolute incontinence Eight months after the operation the patient stated that he could dispense with the urinal, which he had hitherto worn constantly, for a period of twelve hours and that with the assistance of pressure over the suprapubic region, partial evacuation of the bladder was possible

Of course several months are required for physiologic union to take place fully in a case of either peripheral or root anastomosis but the result in this case so far is most satisfactory The operation has also shown that no reason exists why nerve-root crossing should not become a valuable addition to our neural surgical procedures, not only for the relief of paralysis of the bladder and bowels of organic origin, but also for obstinate and distressing enuresis of unknown cause The operation also has a field in some forms of residual paralysis after poliomyelitis and probably in some monoplegias of central or peripheral origin

REPORT OF CASE

J S G, aged 27, married, was a business man who had always had unusually good health until he met with an accident, July 6, 1911 A large gas tank exploded in a shop in which he was at the time He was thrown some distance with much violence and was rendered unconscious, remaining

---

* Read in the Section on Nervous and Mental Diseases of the American Medical Association at the Sixty Third Annual Session, held at Atlantic City June 1912.

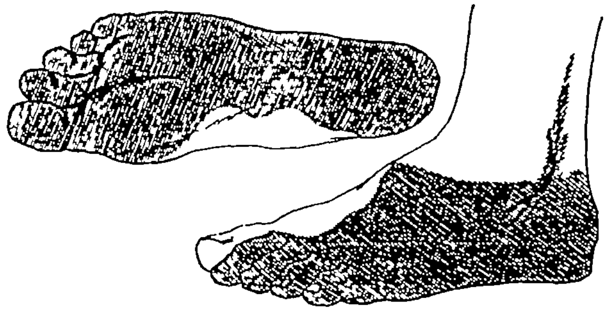
so for five or six hours He was taken about thirty or forty miles to a hospital

He had lost power in both lower extremities Immediately after the accident his feet were very sensitive to pressure, so much so that it was impossible for him to have his stockings put on His bladder and bowels were paralyzed He had to be catheterized for four weeks He gradually improved, especially as regards power in his lower limbs, but certain very positive conditions remained when he was first examined by us The loss of power in his lower extremities showed itself then simply in an inability to lift himself and stand on his toes and fore part of his feet, the impairment being therefore chiefly in the calf movements

His bladder continued paralyzed and in consequence of this he had absolute incontinence, and he had also developed some cystitis His bowels were torpid, although not so bad in this respect as at first When they were opened by the use of a cathartic he could not fully control the evacuation

About a week after the accident he suffered much pain in his back This disappeared, and he had not had any shooting pains or girdling pains along the spinal column He had no reflex spasms or jerkings in the lower extremities

Several examinations gave the following results Station and gait were good In attempting to stand on the toes and fore part of his foot he had evident difficulty, although able to perform these movements For a long time, as above indicated, he was not able to stand in this way at all Examination of separate movements of the foot showed that he could abduct, adduct, dorsal flex, plantar flex and perform movements of all possible description on the ankle The power to elevate the heel was slightly impaired Extension and plantar flexion of the great toe and other toes were preserved All movements of the leg on the thigh and the thigh on the abdomen were preserved and well performed Knee jerk on the right was present and normal, on the left it was much impaired and sometimes absent Both ankle jerks were absent His great toes remained in a slightly extended position but no Babinski response was obtained, and indeed no reflex whatever was obtained on both dull and sharp stimulation of the sole Examinations for touch, pain and extreme heat and cold showed that these forms of sensation were lost over the sole of the left foot except on an area of its inner aspect, the same being true of the dorsum of the foot except along its inner border (Fig 1) The areas of impairment reached about as high as the internal malleolus On the right foot similar areas were impaired, but impairment or loss was more marked over the toes (Fig 2) Callus on the dorsum of the right foot at the metacarpophalangeal articulation had been present, according to the patient, since he began wearing shoes after the accident Sensation was lost over the right buttock and thigh, in an approximately saddle shaped area which gradually decreased in width to its termination an inch or two above the popliteal space On the left a somewhat similar area was present but was narrower and shorter reaching only to a point just below the gluteal fold (Fig 3) The scrotum was also anesthetic An impairment of sensation was present in the coccygeal and anal region



Figs 1 and 2 —Areas of impaired sensation on sole and dorsum of left foot.

A study of the areas of anesthesia indicated that the nerve roots or segments of the cord involved were for the feet, the fifth lumbar and first sacral and for the buttock, scrotum and anal region, the second and third sacral, probably the fourth and possibly the fifth

The patient's greatest distress was by far that which resulted from the paralysis of his bladder, with distention and overflow He constantly had to wear a urinal He thought that the power to expel the urine had not improved but the inability had probably increased to some extent, while in other respects he was conscious of much improvement His sexual powers were practically abolished His feelings of numbness in the feet, and his weakness in trying to stand on his toes he was sure were decidedly less, continuous improvement having taken place He expressed himself as being quite able to stand all his other afflictions if he could only get rid in whole or in part of the distressing bladder trouble

The patient was admitted to the hospital of the University of Pennsylvania for further investigation Roentgen ray examinations were made by Dr H K Pancoast, who reported a fracture of the right half of the first lumbar vertebra

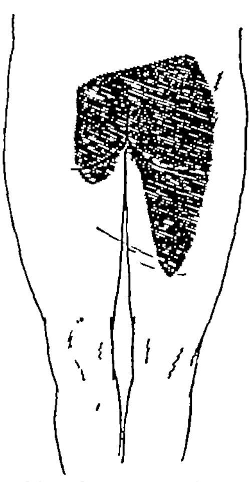


Fig 3 —Areas of impaired sensation on back of the thighs

After much consideration of the subject with the approval of the patient's brother, who was a physician, and with the urgent approval of the patient himself, it was determined to try to anastomose the twelfth thoracic or the first lumbar root to the third and fourth sacral roots It was recognized that nerve anastomosis offered the only hope for the patient's relief and as this was anatomically impossible outside of the vertebral canal, it was thought that it might be accomplished intradurally

The operation was performed by Dr Frazier, Feb 29, 1912 The following were the notes made by him at the time of the operation and the subsequent hospital records

Laminectomy — Intradural Anastomosis of the First Lumbar and Third and Fourth Sacral Roots —Through a curved incision a cutaneous flap was reflected and the spinous processes and laminae of the twelfth thoracic and first and second lumbar vertebrae were removed Evidently there had been a fracture of the second lumbar vertebra, as several fragments were found quite loose and readily detached The dural sac seemed unusually distended, and when it was opened a considerable quantity of cerebrospinal fluid escaped (from 1 to 2 ounces), even though the patient was in the reversed Trendelenburg position with the level of the head considerably below that of the pelvis Inspection of the cord revealed no evidence of injury There were no adhesions, no areas of softening, in fact no abnormality that could be detected with the naked eye After consultation with Dr Mills, I decided to carry out the plan which we had considered carefully before the operation and had submitted to the patient's brother It was intended to effect an anastomosis between the twelfth thoracic and third and fourth sacral nerves intradurally

With the assistance of Dr Edward M Williams, using a unipolar electrode, the other, a large pad electrode being closely applied to the shoulder of the same side the twelfth thoracic and the first lumbar were stimulated within the dural sac, and the one distinguished from the other by the fact that the contractions in the case of the twelfth thoracic were confined altogether to the trunk and abdominal muscles, while in the case of the first lumbar they were associated with contractions of the extensor group of the thigh Attention was then turned to the conus for the purpose of identifying the third sacral root What was taken to be the second sacral was first picked up on a blunt hook, and its faradic stimulation was followed by contractions only of the big toe on the affected side On the ground that we were dealing with the second sacral, the next two nerves adjacent to it and to the inner side were selected for the anastomosis As it was found by measurements that the twelfth thoracic, even if divided extradurally from its point of exit from the canal, would not reach the conus, it was decided to use the first lumbar The latter was divided extradurally at its exit from the spinal canal and brought within the dural sac through a transverse incision in the dura An end to end anastomosis was effected by a single No 1 Chinese silk suture

After the nerves had been identified by faradization, pads saturated with a 4 per cent. stovain solution were kept applied to the cord in order to block, if possible, any harmful impulses

Toward the latter part of the operation the patient's respiration became very shallow and feeble, but on changing his position to his side and resorting to moderate stimulation, normal respiratory function was promptly restored The dura was closed with a continuous silk suture, and the musculoaponeurotic layer with buried catgut sutures The usual cigaret drain, together with a small wick of iodoform gauze, was introduced through a stab wound down to a point of bleeding from the vertebral veins

The operation was necessarily long and tedious, but at no time were any special difficulties encountered, except in one instance when a vein was divided at the time the first lumbar root was cut This was followed by quite free bleeding, readily controlled, however, by a tampon

The identification of the various roots was simpler than had been anticipated The anastomosis was effected on the left side only, where the sensory evidence indicated less injury to the cord or nerve roots

On March 4, 1912, the patient complained of deep seated pain in his thigh, making him gasp His ankle felt stiff and sore He thought also he could feel urine accumulating in the bladder

On March 11, 1912, Dr Mills examined the patient without moving him from a recumbent position Flexion, extension and other movements of the thighs were good and all the movements of the feet and toes were present, these having been tested in detail, the only weakness shown was in dorsal flexion and abduction of the right foot, this being only a partial loss The knee jerks were absent and there was no Babinski response on either side Slight plantar flexion of the toes occurred on plantar stimulation

Tactile sensation, tested by light touch of the finger, was everywhere preserved on the feet and legs below the knees Pain sense tested by pricking was defective in definite similar areas on both sides It was lost on the soles of the feet except the inner side about the hollow of the foot half way between the roots of the toes and the heel On the dorsum it was lost entirely on the inside over all the toes In a linear area from the metatarsophalangeal articulation three or four inches toward the instep, about the instep and toward the internal malleolus, this area of retained sensation was enlarged On the outside of the foot a tongue of analgesia extended an inch or two above the ankle As we were unwilling to move the patient at this time he was not examined over the buttocks, thighs, etc

On March 27, 1912 the patient was discharged He felt distention of the bladder on the introduction of 10 ounces of boric solution but he did not feel less amounts of boric solution or of urine

As stated at the beginning of the article, eight months after the operation the patient could dispense with the urinal, which he had hitherto worn constantly, for a period of twelve hours, and with the assistance of pressure over the suprapubic region, partial evacuation of the bladder was possible[1]

NERVE SUPPLY OF THE BLADDER

According to Frankl-Hochwart,[2] whose monograph on the "Nervous Diseases of the Bladder" is among the most reliable and most recent (1906), the bladder has two or three sources of supply In the first place it has a supply through the sympathetic nervous system Efferent nerves pass by way of the rami communicantes from the upper lumbar segments of the cord according to Langley and Anderson (at least in the cat) These take their course through the lumbar sympathetic to the inferior mesenteric ganglia From these inferior mesenteric ganglia three gray hypogastric nerves penetrate the muscles of the bladder Another sympathetic supply is from the upper sacral segments and roots These nervi erigentes go to the hypogastric plexus From this plexus, according to Griffith, the fibers pass in three layers, one to the fundus, another to the anterior part of the bladder and around the neck, and the third to the vesical part of the urethra

In the human being, according to Frankl-Hochwart and Russian and other authorities with whom he agrees, the somatic nerves to the bladder are from the third and fourth sacral segments and roots

Kilvington[3] has published the only article on nerve crossing within the spinal canal with which we have become acquainted In this article he first briefly discusses the fact that regeneration does not take place within the spinal cord, referring to the well-known fact that it seems to be necessary for the primitive sheath to be present in order that such regenerative processes may proceed He then affirms that such regeneration may occur when nerves are united either intradurally or extradurally within the vertebral canal

Experiments were made on several dogs in order to test the possibility of bringing about restoration of the functions of the bladder and rectum through nerve crossing and subsequent regeneration Attention is called to the facts shown by various physiologists, as Langley and Anderson and Sherrington (cited by Schäfer[4]) that in the dog the nerve-supply to the bladder and rectum is chiefly from the second and third sacrals and sometimes from the first sacral and even the seventh lumbar. According to Kilvington the second and third sacral nerves always give bladder contraction sufficient to expel the contents, although the first sacral in a few cases gave bladder contraction, but not enough to cause micturition

Kilvington's instructive experiments on three large dogs and their results are recorded by him in detail In his summary of these experiments he concludes that it is shown that the last lumbar, when joined to the second and third sacral roots, on electrical stimulation can produce all the effects which the latter give on the untouched side

After Kilvington had determined by investigation on the cadaver the feasibility of intraspinal root anastomosis in man, Mr Bird at his suggestion attempted the operation in one case, this operation proved unsuccessful because of conditions found after the laminectomy

In his experiments on dogs Kilvington in two instances anastomosed both motor and sensory roots (a mixed nerve in effect) to motor and sensory roots below In another experiment he crossed the anterior or motor root above with both sensory and motor roots below In the case recorded in this paper we anastomosed a motor root above with a motor and sensory root below

Certain disadvantages might arise from mixed anastomoses It is doubtful whether in the surgical procedure the motor root above could be properly apposed to the motor portion of the mixed nerve below Again,

---

[1] The patient has reported once since the presentation of the paper—in June—that he is now able to retain urine for two and a half hours at a time and that the expulsive power of the bladder seems a little greater than at the last report

[4] Schäfer Physiology ii, 342.

if an anterior root as in one of Kilvington's experiments, were crossed with both sensory and motor roots below, the only physiologic result, if the procedure were successful, would be the transfer of motor impulses A motor root of one distribution might physiologically as well as anatomically unite with a motor root belonging to another segment of the cord, but it is doubtful whether a motor root would physiologically combine with a sensory root even if they were brought into physical union

A sensory root may be combined anatomically and physiologically with a sensory root of its own sort, but it may be questionable whether a somatic sensory root will serve to take the place of a destroyed visceral sensory nerve

Our idea in this operation was to perform an experiment in anastomosis for the relief of the paralysis of the walls or sphincter of the bladder, or of both, similar to that which has been performed extravertebrally in cases of poliomyelitis, traumatic severance of peripheral nerves and other paralyses The bladder is a muscular organ with a motor nerve-supply, which in large part at least is similar to that of muscles everywhere in the body, although it does in part, as has been shown, receive its innervation through the sympathetic nervous system By uniting a motor root which is a part of a healthy reflex arc with the motor root of a destroyed sensorimotor region of the cord, both the sensory and the motor portions of the intact arc are utilized In addition the muscles supplied by the first lumbar nerves in the human subject probably have some accessory value in bladder function

PRACTICAL SUGGESTIONS

We have discussed the physiologic problems involved in the reestablishment of innervation to the muscles of the bladder, and the operation as performed has been described Such features as apply only to matters of technic remain to be considered There is little doubt as to the advisability of a bilateral laminectomy when the identification of roots requires ample exposure and when, as in future cases, we would expect to effect anastomoses between the roots on both sides It is often difficult to determine the exact position of an individual vertebra, so that in the future we would make sure of this before the operation by having a radiograph taken with a lead strip over what was believed to be the first lumbar vertebra This would enable the operator at once to be able without the use of the electrode to identify the first lumbar root which leaves the vertebral canal in the foramen between the bodies of the first and second lumbar vertebrae Therefore the identification of the third or the fourth sacral root would alone remain, and this could be done with any degree of scientific accuracy only by the use of the electrode, as the massed roots composing the conus could not otherwise be distinguished one from the other It was suggested by Dr E M Williams at the time of the operation that with the bladder filled with boric solution and a small manometer connected with the catheter, stimulation of the third and fourth sacral roots would be followed by an expulsive effort on the part of the extrusor muscles of the bladder which would readily be recorded on the manometer This is an excellent practical suggestion and will be taken advantage of at the next operation No difficulty should therefore be experienced in the future, in promptly recognizing the roots to be used in the anastomosis, and needless to say the anastomosis should be effected on both sides and not on one only, as in the case reported

The principles involved in suturing the divided roots in no wise differ from those which have been laid down for anastomosis of peripheral nerves, it should always be borne in mind that extreme gentleness the avoidance of trauma, the employment of proper suture material, absolute hemostasis, and the absence of infection are essential to success

It would be out of place here to discuss in detail the technic of the preliminary laminectomy It will be sufficient to emphasize two points which we regard as of importance in minimizing the risks of operation In the first place, we have found the method of administering the anesthetic by intratracheal insufflation to possess great advantages over the drop method not only for safety but also for convenience We place the patient in these operations in the prone position with the table elevated to an angle of 45 degrees from the waist to the foot, and with the trunk and head in the reversed Trendelenburg position This position is convenient for the operator and at the same time through the influence of gravity prevents the continuous outflow of cerebrospinal fluid It is a well-known fact that in prolonged operations when the patient is in the prone position (face down), the respiratory apparatus seems to wear out more readily, and under ether anesthesia proper oxygenation of t[illegible] terfered with The use of intratracheal [illegible] ly overcom[illegible] diffi

Predementia præcox is a condition which may also be acquired by faulty mental habits, and the close study of the school child which I have advocated will not be half so efficacious if cognizance is not taken of his emotional control and his attitude toward his associates and the world in general.

It seems unnecessary to point out how great a factor in the making of a better nation may be the training of the individual to fit into the place in life which he can most ably fill. A half moment's thought will convince you of it more clearly than I can with half an hour's talk.

The psychiatrist rarely sees these early cases. The teacher is the first one to observe them, the general practitioner comes second, perhaps the neurologist third, and the psychiatrist usually after symptoms are well advanced and the patient is suffering with an acute mental attack. At times, however, a case comes under our care during the prodromal period of an acute attack and we may be so fortunate as to abort it. After the acute attack much may be done by reeducation, especially along the lines of manual training of various sorts, and we are able to make something of the patient, even if less than he would have been had he not suffered his attack. Did time permit I could give numerous case-histories illustrating the value of reeducative methods, but, as it is, I can only refer you to the few objects which are on exhibition to illustrate this point more strikingly.

CYANOSIS IN DEMENTIA PRÆCOX *

WILLIAM BURGESS CORNELL, M.D.
Assistant Physician Danvers State Hospital
HATHORNE, MASS.

The trend of recent studies in dementia praecox has been toward the physical manifestations of the disease. The earlier writers concerned themselves mostly with the mental sphere and would make their diagnosis chiefly or solely on mental symptoms. But of late, independent of the psycho-analysts and those who urge a more or less strictly psychogenous origin, investigators of another and more material group, working from a physical point of view, have brought to light an array of clinical and objective signs which seem to be of great diagnostic importance, and will eventually, it is felt, assist in determining an etiology in this disease, the frequency and sociologic importance of which is only beginning to be appreciated by the general medical profession.

Omitting the pathologic and biochemical findings, the clinical signs of recognized value are: alteration in the deep tendon reflexes, increased at first, diminished or absent in late stages; irregular pulse, rapid in some instances, in others markedly slowed; excessive salivation, and variations of temperature, subnormal in some cases, elevated often in acute stages. Considerable work has been done on the ocular symptoms, among the most interesting being that of Tyson and Clark,[1] who report an "eye syndrome" peculiar to dementia præcox, embracing concomitant changes in the disks, pupils, visual fields and corneal sensibility. Others have called attention to the pupillary phenomena, consisting of abnormalities in size, outline and light reaction. In acute phases dilatation is frequently seen and in late stages a contracted, sometimes spastic pupil with inequality, irregular outline and ragged edges. Changes in the light reflex are frequently observed, especially in the terminal stages. Still others have described abnormalities in the skin, including hyperhidrosis, subnormal temperature, altered dermatographia and cyanosis. It is with cyanosis in particular that this paper is concerned.

A cutaneous cyanosis occurs in a number of diseases quite distinct and independent of that under consideration. It is observed in apparent health under transitory vasomotor conditions, but its frequent presence in dementia præcox without cardiac involvement would suggest that we have in this a sign but little less than pathognomonic. My interest in cyanosis began in the daily morning clinics at Danvers where patients are presented for diagnosis. The cyanotic hands of dementia præcox patients are in marked contrast to those of patients with other mental diseases, and inspired an investigation which has convinced me that cyanosis is a highly valuable diagnostic sign, especially when taken in connection with other symptoms of the malady.

During the past year 241 patients with dementia præcox, embracing all types and stages, were examined, and 78 per cent. were found to have some grade of cyanosis, from a mild degree to an extreme dusky purple. The distribution varies, being usually most marked over the dependant parts, yet the skin as a whole often has a bluish appearance, more noticeable in the upper back. The relative frequency of involvement of the hands, feet and back is as 9: 6: 5. Some patients may show cyanosis of the feet when there is none on the hands, and vice versa. Occasionally the face and lips present the most involvement. Cyanosis varies in the same patient from day to day or week to week. It may be absent one day and quite evident the next; this seems relatively independent of the surrounding temperature and the position assumed. The severest grade of cyanosis has been observed in a patient confined to bed. With respect to the three subgroups, in cases in which it was possible to make a subdivision, the catatonic form showed cyanosis in 90 per cent.; the hebephrenic in 75 per cent., and the paranoid in 50 per cent. This was also the relative order of the intensity.

It seems that the grade of cyanosis carries some prognostic significance. The cases deeply cyanosed apparently dement more rapidly and deeply. Acute catatonic excitement with marked cyanosis forecasts grave danger of collapse and death. From the point of view of differential diagnosis, cyanosis offers help when assistance is often badly needed, in differentiating dementia præcox from manic-depressive insanity. It is believed that cyanosis is exceptional in the latter disease, and in thirty cases including depressed, mixed and excited phases only two showed it, in one, a depressed case it was well marked, and in the other, a hypomaniacal case, fairly so. But without doubt, the skin in a manic-depressive has quite a different appearance from that of a precocious dement. Without having the figures to demonstrate, I also believe that cyanosis is of help in differentiating imbecility from dementia præcox, the skin of the imbecile being clear, except when the two psychoses are combined. Two cases might be cited as instances in which the presence of cyanosis helped to revise an earlier diagnosis. One patient, a woman of 35, at first appeared to be in a depressed phase of manic-depressive insanity, but later other symptoms cast doubt on this, and the additional development of a marked cyanosis pointed the way to a dementia præcox which

[1] Tyson and Clark: THE JOURNAL A. M. A., May 2, 1908, p. 1415.

the clinical course of the case confirmed The other case, that of a woman of 37, was provisionally diagnosed as paresis, the Wassermann reaction in the serum was reported suggestive but the cytologic examination of the spinal fluid was negative Later the presence of a marked cyanosis combined with impulsivity and other symptoms led to a reconsideration of the case and to a diagnosis of dementia præcox

What is the nature of this cyanosis? First of all, it does not seem dependent on blood-pressure, as the various investigators of blood-tension in dementia præcox have not reported any departure from normal In twenty-five cases which I have studied the average systolic pressure was 115 for a sitting position and 95 for a reclining position, the markedly cyanosed cases showing no variance from the average We know that we are at least dealing with a vasomotor phenomenon In this respect it is interesting to refer again to Tyson and Clark's paper [1] Their most frequent finding was a congestion of the disks, due to dilatation of the veins, and this is certainly analogous to the cutaneous phlebostasis The ocular syndrome of Tyson and Clark seemed to them somewhat similar to the toxic amblyopia of tobacco and alcohol and led them to the opinion that some sort of toxin, metabolic in nature, was the pathogenic agent, and that this toxin was primarily a vascular poison which led slowly to degeneration of the nerve elements The conclusions of Pighini[2] are somewhat different He believes that in the acute stages there is a destruction of nucleoproteins induced by some unknown morbid agent, and that it is not a typical toxic or destructive process such as seen in ordinary febrile diseases To account, furthermore, for the skin condition in dementia præcox, there must be some interference in the skin reflex arc with more or less disturbance of the vasomotor nuclei which Sano[3] locates in the anterior horns of the cord, but which are located elsewhere, chiefly in the sympathetic, by others The dermatographic reflex would indicate that there is indeed some alteration in the vasomotor innervation for as a rule this reflex is much diminished and occasionally absent In fifty-five cases studied for this point 60 per cent were found to have a diminished reflex

SUMMARY

A cutaneous cyanosis is found in a large majority of dementia præcox cases most frequently and intensely in the catatonic form, next in order in the hebephrenic and then the paranoid

It is part of a generalized vasomotor disturbance consisting in a phlebostasis, of unknown origin

Cyanosis is variable within large limits even in the same patient

Cyanosis offers a valuable diagnostic sign in differentiating dementia præcox from manic-depressive insanity, imbecility, hysteria, constitutional inferiority and occasionally the organic psychoses

---

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS DUNTON AND CORNELL

Dr. M Neustaedter, New York I have had occasion to examine backward children in New York schools for twelve years I find that the physical defects in these cases are less numerous than in the very best children in the schools, and they are not prone to have their defects corrected So far as I remember in over 1,200 cases 2 per cent have corrected the physical defects, and yet with a properly corrected diet and elimination of drugs and narcotics, such as tobacco, coffee and tea and alcoholic stimulants, we have achieved very good results I have followed them in the workshop and I have come to the conclusion that it is not manual labor alone that is required for improvement, it is the geographic and social environment of the child that counts more than anything else If we could take the child from the busy city into farm and country life and give him different ideal surroundings with proper diet, we could do much more for him than by using all the subtle scientific methods in the public schools exclusively in big cities

Dr B R. Tucker, Richmond, Va We see reference to seclusion in the predementia stage, and reference to a child being asocial We should draw a line of demarcation between a child who wants to play but does not enter into the games and occupations of childhood because of bashfulness, which may not overstep the normal line, and the child who is asocial and primarily does not want to enter into the occupations of childhood I have seen children who have been suspected of dementia praecox or some other mental disturbance simply because they were bashful

Dr L Harrison Mettler, Chicago The percentage of dementia praecox cases admitted to the asylums throughout the country has been estimated to vary from 15 to 45 This wide variation cannot be satisfactorily accounted for on the basis of a geographic distribution or a difference of diagnostic ability It indicates a fundamental weakness in our conception of dementia praecox. It would be of the highest practical value if we could discover and establish some physical signs by which we could recognize, or assume, a definite pathologic change in these individuals In diagnosing dementia praecox, in all of its forms I find myself leaning more and more on physical results of psychanalysis What is a defective child? Apparent and real defectiveness are often hard to differentiate The distinction may depend on the relative state of the examiner's own intelligence and mental state Suppose a child is a little backward unsocial, selfish, and of a quick temper, may this not have been the result of bad training, environment or social injustice? Ignorance, both gross and subtle, is so widespread, it seems to me that it, more than organic defectiveness, can be invoked to explain in many cases the traits that are being given to us by overenthusiastic investigators as evidences of such defectiveness

Granting that we can, along certain coarse lines, diagnose the defective child, what shall be the mode of its training? Manual training is just now in high vogue for such cases, and for most of them I have no doubt it is the proper thing Manual training, however, is not a panacea or antidote for mental defectiveness I have seen instances in which I thought the recommendation of manual training was evidence of more mental defectiveness in the adviser than in the subject Suppose a child has certain marked and exceptional tendencies of an elementary character along the lines of art, music, literature or mathematics, it is conceivable that such a child might be regarded as a bit defective, and be most unfortunately set to nailing up boxes and constructing peach baskets by a medical examiner whose thinking outside of his profession, scarcely ever went beyond golf and bridge whist In so broad and uncertain a field as the care of the defective child, the physician is liable to find his limitations for making a correct diagnosis and advising a judicious line of treatment more glaringly revealed than in any other branch of his professional work The class of children first referred to should be saved from incompetent and inadequately educated experimenters The harm they will do in squelching a mind that is normal, but not developing along old conventional, humdrum lines, will outweigh the little good they may accomplish with their manual teaching when they do have a defective child to care for

Dr George H Moody, San Antonio, Tex I have observed that it is very difficult to avoid the tendency to blend vaguely feeble mindedness in children with dementia praecox Are we going to allow ourselves to call some of the feeble minded children dementia praecox patients, or is a dementia praecox a distinct disease separate from feeble mindedness? Of course we often see and understand that dementia praecox occurs in children who are constitut nd that the latter superimposed condition hile the original inferiority never can

---

[2] Pighini Riv sper di freniat 1908 iii iv 497

[3] Sano Jour de Neurol 1910 Nos 15 16, 17

We are frequently asked for a prognosis in cases of dementia praecox If we are to distinguish dementia praecox from feeble mindedness then we are going to give a different prognosis If we separate the two conditions when they occur in the same individual, which often happens, it seems to me that we can frequently tell the parents that perhaps the child will regain the condition which has been normal for that child, but if the parents expect a child with dementia praecox to overcome its natural mental inferiority as well, provided it be congenitally inferior, and come up to the normal intellectually, physically and every other way, of course we must tell them that it cannot recover It is important to avoid the blending of weak mindedness in children with the beginning of dementia praecox With this strict avoidance there will be a greater percentage of recoveries in our dementia praecox cases

Dr H. A Cotton, Trenton, N J The variation in the number of dementia praecox cases in the various institutions may be ascribed to two factors first, errors in diagnosis, which are liable to occur in any institution in which they are not well acquainted with the disease, second, there is a distinct difference in different localities At Danvers, Mass, we had a pretty large proportion of dementia praecox cases, and I rather favored the diagnosis of manic depressive insanity Still, there were many cases diagnosed as dementia praecox At Trenton, N J, where the persons of foreign descent are much fewer than in Massachusetts—a large proportion of our patients were of Irish descent of first and second generation—we have perhaps the smallest proportion of dementia praecox cases because the locality, the type of population etc, have something to do with it

I agree with what has been said about the necessity for recognizing these other cases, and doing something before the patients come to the institution We have them as they come into the hospital, when they are from 7 to 10 years old, after the onset of the acute stages of the trouble, and I think we are in the same position now with regard to dementia praecox that we were with tuberculosis some years ago, when the physician, having said 'consumption," sounded the death knell of the patient, while to day we know that if the symptoms are discovered early a large proportion of the patients recover So with dementia praecox, when we are able to give symptoms and show conditions which need attention in the early stages, then we will be apt to have more results from the family physician

Dr C B Burr, Flint, Mich I think we should hesitate to exalt into a differential diagnostic sign something which may be present in a variety of nervous conditions or which may depend on transitory, momentary conditions of muscular activity and perhaps on emotional states I have not observed the connection of which Dr Cornell speaks, but, of course, we all recognize cyanosis as an accompaniment of depressed nervous conditions If it is true that we can by a little more attention to cases discover that this is a sign enabling us to differentiate between manic depressive conditions and those of dementia praecox, we shall be deeply indebted to Dr Cornell for bringing the subject to the attention of the Section

Dr. E E Southard, Cambridge, Mass Some years ago I undertook an analysis of anatomic material in dementia praecox To get a list of cases to work with I selected from the autopsy list all cases denominated dementia praecox, and before investigating them anatomically I looked them over clinically to make sure that I had a convincing list I started with sixty three I did not think, however, that I could persuade my professional brethren of the existence of dementia praecox in many of them, and finally I got a selected list of twenty nine, which I thought were really cases of dementia praecox The others were possibly affected by alcohol, or by imbecility, or by the probability of an erroneous diagnosis in the direction of manic depressive insanity, and even in the cases which I finally analyzed anatomically, there were a number of phenomena in the brains which would lead one to think that several of the cases were at least, as we say, on the imbecile basis There were evidences of hypoplasia or congenital alterations in the brain in some of the cases The percentages I have forgotten but the diagnosis was difficult I rather feel as if we could talk concretely about the catatonic form and the hebephrenic form Paranoid forms make up statistics on these forms rather than the total group, and there is a large number of cases allied to dementia praecox

Dr W R Dunton, Jr, Towson, Md. I do not want Dr Neustaedter or any one else to understand that I simply advocate manual training treatment I speak of that as typical of the sensory training which we want to give these patients, and the geographic and social environment and everything else must be considered very strongly A bashful child, I think, needs study to discover the cause of the bashfulness The unsociability of a bashful child is simply a sign, and to my mind those cases should be studied The personality is a strong element Certain physicians will not diagnose cases of dementia praecox unless the dementia is extreme, that is, until the terminal stage is practically reached As for diagnosing the disease in the predementia stage, it never enters their minds If there is a remission (and we all know that remissions occur frequently) they do not believe that the case is dementia praecox—it must be something else (because the patient has recovered!)

I do not agree with Dr Moody about the confusion of feeble minded and dementia praecox cases I think the distinction can ordinarily be made But we must remember that feeble minded persons occasionally have attacks of dementia praecox The cyanosis has always suggested to me a faulty metabolism

"Allied dementia praecox" is an unfortunate term, and the sooner we drop it from our classification the sooner we will come to a more exact understanding of this condition if every one will remember that the cardinal symptom of dementia praecox, the most important thing to bear in mind in case examination, is apathy, the patient's emotional indifference, I think we will come to a definite understanding sooner than if we use the term, "allied dementia praecox "

Dr W B Cornell, Hathorne, Mass Dr Southard spoke of the difficulty of diagnosis and the personal element connected therewith, but every step toward the establishment of definite clinical signs tends to eliminate the personal element and the resulting errors I am inclined to lay considerable importance on the physical findings in this disease Dr Moody asked regarding the occurrence of cyanosis in weak mindedness and if dementia praecox bears any relationship to the latter I think that dementia praecox and imbecility or weak mindedness are quite distinct, but they may be combined, and in such cases cyanosis may be seen frequently I am indebted to Dr Burr for his questioning the value of cyanosis as a symptom in psychiatry Often I have doubted its value myself, but now I really think that it is of importance particularly as a diagnostic sign in cases of acute catatonic excitement in which cyanosis is often quite marked and calls attention to the necessity of circulatory stimulation

I have no data on the occurrence of cyanosis in epileptic cases

---

MEDICAL EDUCATION IN SOUTH AMERICA

JACOB FRANK, A M, M D
President of the Chicago Medical Society
CHICAGO

Last winter, having contemplated a trip to South America I was appointed by Dr A M Corwin, chairman of the Chicago Medical Society Council Commission on Medical Education of which I am a member, to obtain data regarding the medical schools in the countries which I should visit I also received a similar request from Dr N P Colwell, secretary of the Council on Medical Education of the American Medical Association It is to record briefly my findings in this direction, as far as I could obtain knowledge of the facts on a hurried visit, that this article is written

I left New York Jan 20, 1912, and arrived at Buenos Aires during the height of the Argentine summer, when the colleges were all closed and many of the faculty members away on their vacations The weather was sweltering, but I was able to find well-informed physicians and through Spanish and Portuguese interpreters obtain information

I was received with great courtesy by our Southern colleagues, who made every effort to show me their hospitals and schools and to give me all the information that I asked for They demonstrated that the proverbial reputation of our neighbors of the Latin-American countries for hospitality and courteousness is well founded

I visited the schools and hospitals of Brazil Uruguay, Argentina and Chili, and was told about the medical schools of the other countries of South America that I did not visit

The medical department of the state university at Buenos Aires is the best school in South America and will compare favorably with any school on this continent or in Europe The city of Buenos Aires is thoroughly cosmopolitan, having 1,350,000 inhabitants and a history dating from the sixteenth century It is well to remember that the oldest civilization of Europeon origin in the western hemisphere is Latin, and that many cities to our south antedate the oldest in the United States

The medical university at Bahia is the oldest and one of the most noted institutions in Brazil, having been established by Regent Don João, who visited Bahia in 1808 It will be remembered that the first medical school in the United States was the one at Philadelphia founded by Dr John Morgan in 1765 The personal physician of the royal family founded the institution at Bahia, which was called the Collegeo Medico-Chirurgico, the first lectures being delivered in the military hospital of Bahia In 1832 it was installed in a suitable edifice of its own and the course of studies was enlarged It was not until 1882, however, that it became known as one of the best medical institutions in South America During that year it was completely reorganized by the emperor Seven new chairs were created, making the whole number twenty-six New laboratories were opened, and medical and surgical training was improved In 1901 a chair of bacteriology was created and an experimental laboratory established in this department.

The curriculum is divided into twelve sections, embracing all branches of medicine, and the course of studies extends over six years, special attention being paid to clinical teaching which is given in the Misericordia and other hospitals as well as in the clinical institute of the faculty, which is comparable to our own dispensaries The building for this work is lighted by electricity and equipped with many modern conveniences This is the smaller of the two medical schools of Brazil The charitable institutions of Bahia, in which the students receive their clinical training, are governed by the central board of health which has charge of the hospitals, the disinfection department the city service and the vaccine institute

The other medical college of Brazil is located at Rio de Janeiro and, though younger, is much larger It also has a six-year course and has about 1,000 medical students The population of this city is 850,000 The students of both of these colleges have the privilege of attending either of them in any department Both institutions are under government patronage, but are subject to proprietary control of the faculty which regulates the curriculum The salaries of the older professors are still paid by the government, but the newly appointed professors are remunerated from the income of the school itself

Up to one year ago the grade of both these institutions was decidedly low as compared with our own standards or those in other parts of South America, but within this period a thorough reorganization has been effected on the lines of the medical universities of Germany

The government, in addition to salary appropriations, allows a considerable sum yearly toward the running expenses As an entrance requirement all students must know Portuguese, their own language, and in addition any two foreign languages, the preference being given to French and German The lectures are delivered in Portuguese, but most of the text-books are of French and German authorship French is preferred by the students

The medical course is of eight months' duration, from April 1 to December 1 Formerly examinations for degrees were written, but of late all tests are oral, each student being required to discourse for fifteen minutes before the examining board These innovations seem to prevail in all the colleges of South America, and the reason given is that under the written system "cribbing" could not be controlled

The resident surgeon of the state hospital (which is similar to our Cook County Hospital) is paid by the government, his assistants receive part pay from the same source and the remainder from the medical faculty It should be said in justice to the Brazilian medical schools that though they have been of low grade compared to those in Argentina, Uruguay and Chili and the average in our own country, they are now endeavoring to place themselves on a par with the best in South America in equipment, buildings and requirements

In passing from tropical Rio de Janeiro to temperate Argentina we find a radical change for the better in the status of medical education and practice There are two schools in the latter country, *one at Cordova and one at Buenos Aires, both under national control and* management The proprietary school, therefore is unknown and not allowed There are at least from 1 500 to 2 000 students in the medical department of Buenos Aires University The admission requirement is a secondary school diploma, the medical course *extends over seven years, the curriculum being thoroughly* graded for each year The examinations are all oral, and no thesis is necessary There are thirty-two examinations of half an hour each before a commission of three professors appointed by the dean The examinations are severe and must be passed in the Spanish language They take place twice a year, the first for all students and the second for those who did not pass, third, there is a special examination for foreigners, who must present a diploma from their own country viséed by some home authority and by the local Argentine representative from the home country After this they are admitted to examination, and must pass all the studies included in the curriculum of the seven years, all the examinations are held in Spanish The fee for examination is $1,000, Argentine money, I think It is perhaps worthy of note that foreigners are permitted to practice in rural districts provided there are no local Argentine physicians, but permission must be secured from the board of health to practice This is evidently to enco[illegible] l practitioners in [illegible] outlying district[illegible] ol[illegible] handsom[illegible] are to be had [illegible] at c[illegible] examiners [illegible] ernment

The profession is not so overcrowded as it is in the United States, though I was unable to secure statistics on this point. French text-books are used and some German, but no English. The English language is not spoken or understood. The text-books in surgery are in French.

There are two rival medical societies in Buenos Aires. There is no characteristic student life, and no medical clubs or fraternities exist. Drinking and dueling among students are unknown. There seems to be a distinct antagonism between Argentine and foreign practitioners, notwithstanding the notable courtesy extended to me.

All interns are chosen from the best among the sixth and seventh year students. The professors are appointed by the minister of education, but as a rule are recommended by the faculty. All are paid for their services.

A good many students finish their education in Paris or Berlin. There are no postgraduate schools in Argentina. The government annually sends certain students to Europe at government expense and I think only one has been sent to the United States recently. American colleges might do well to cultivate this field, not only to bring to the attention of South Americans the superior work done in the United States, but to stimulate better international intercourse between the various Latin-American countries and our own. The late Nicholas Senn did much to encourage Japanese medical students seeking medical education to direct their travels from France and Germany to our own shores. Had he lived it is safe to say that the largest percentage of these would have been in American schools to-day.

I well remember that when I was on my trip around the world with him, about ten years ago, a banquet was given in his honor at Tokio by the government. On a side table was a collection of all the works which were the product of his active and virile pen. The honors accorded him and the attentions shown him were princely, and the eulogies pronounced to his fame as surgeon and teacher far surpassed anything that I have ever listened to.

In response, he dwelt forcibly and at length on the advantage to be gained by Japanese medical students in coming to our country. With him this was a sacred conviction born of his national pride. It would have done your hearts good to listen to the patriotic spirit which he voiced that evening. If to-day we had others of his kind, the United States would soon be the Mecca of our Southern, as well as of our Western neighbors across the seas.

To return to the school at Buenos Aires: the buildings are large, spacious, well lighted and richly equipped with all the modern appliances for comfort and superior work. They are well stocked with apparatus of every description, scrupulously clean and in order, and are patterned after the best in Europe. Laboratories, departments for the specialties, dissecting-rooms, etc., are prodigally planned and lavishly equipped. Good use is evidently made of it all, though I cannot vouch for this because it was in the vacation season when I visited them.

The reason that they can do these things on so great a scale is the government control and the large sums of money that are received for this purpose from race-courses and lotteries which are sanctioned by the government and universally patronized.

Buenos Aires contains hospitals aggregating about 5,000 beds freely accessible to all medical students of the fifth, sixth and seventh years; here the students receive their clinical training.

The other medical school of Argentina is located at Cordova. It is much smaller than the one at Buenos Aires, but the requirements, government control and management are similar. There are no proprietary medical colleges in Argentina. In Uruguay and Chili the system of medical education is substantially like that in Argentina, but in Paraguay, I was informed, medical training is bad.

Venezuela has two medical colleges, one located at Caracas and one in Ciudad Bolivar, the former having only forty or fifty medical students, the latter twenty-five or thirty. The course of medical instruction in these institutions extends over a period of three years. Both faculties are small and inefficient and their curriculums and requirements are far below par. The oldest hospital in South America is the Misericordia at Caracas governed by the Sisters of Charity.

Boys of 16 and 18 years of age are allowed to study medicine in Venezuela. In spite of this evident lack of preliminary education many of them I am told are wonderfully keen, have analytical minds and grasp ideas readily; they can converse on medical affairs fluently and intelligently but do not tend to carry out in practice what they learn.

Cadavers in Venezuela are not preserved as with us. Fresh subjects are taken and worked with as quickly as possible in order that they may be disposed of the same day. This is done because of the heat and moisture of the atmosphere which rapidly disintegrates the bodies. Subjects are numerous and easily procured, as all deceased indigents are turned over to the dissecting-rooms if wanted.

Caracas is a city of 100,000 inhabitants and contains only about 100 physicians. There is a need of good physicians in Venezuela. The native physicians are not prosperous because of the custom among them of allowing patients to pay whatever they wish. Foreign practitioners make specific charges and the people have more faith in them and look up to them as being more highly educated. There is no state medical association, but local societies exist as with us. Suits for malpractice are unheard of among these natives. It is ethical for physicians to advertise in the daily press and give testimonials for patent medicines.

There is a leper hospital of 400 beds in Caracas. The patients go and come as they please. Twice weekly those who are able go about and can be seen begging in the streets. On market days it is a common sight to see them vending vegetables.

A law exists in Venezuela against unlicensed practitioners. Non-graduates can procure licenses on examination but must practice in the rural districts, where they are numerous. Birth-certificates are not compulsory, but death-certificates are. Indian doctors are allowed to practice as they choose and the law does not interfere with them. Love potions to bring lovers together are common prescriptions, and strange to say, as in America, these fakers are patronized by some of the best families.

Generally speaking, in South America schools for nurses are wanting, and, while the Sisters are very charitable, they lack efficient training in the up-to-date, modern, scientific care of the sick. Male patients are universally attended by male orderlies. I was impressed with the fact that everywhere hospital accommodations are below requirements. I saw in almost all the state hospitals many patients lying on the floors, so manifest was the overcrowding The good sanitary condition, however, which has been established in the sea-coast cities within the past five or six years, is in notable contrast to the former state when the cities were recognized pest-holes These reforms are in large measure due to the fact that medical men are at the head of many South American municipalities For example, the major of Rio Janeiro is a physician, and is proud of the sanitary measures which he has inaugurated in that city Well may he be, for it is one of the cleanest cities that I have ever visited

In conclusion I may suggest that the holding by American physicians of the offices of mayor, alderman, governor and other executive positions is needed to place us on a par with members of our profession in other parts of the world where they are in the van of progress as leaders in politics, and in economic and social affairs It is for this leadership that our higher medical standards and training fit us

32 North State Street

A SERIES OF INFANTS FED ON A HIGH-PERCENTAGE ALBUMIN MILK *

FRANK C NEFF, M.D
KANSAS CITY, MO

The work of Finkelstein and his school in the use of *Eiweiss-Milch* in the nutritional disorders of infancy is now too well known to need narration Many of you have seen this food used at the Berlin Kinderasyl or elsewhere, many personally have tried it, and all have read the growing literature on the subject That it has a temporary value in selected cases is accepted by most observers That the dyspeptic stools improve and that with the addition of malt sugar the infants begin to gain in weight is the experience in most cases

It is my purpose in this paper to record observations on the administration of a milk which is prepared according to the method of Finkelstein but in which the whey-elements have been increased beyond those of the regular albumin milk The food which I have used is therefore *richer in proteids, sugar and salts* This has been attained by using all buttermilk as the diluent for the curds instead of half buttermilk and half water

The analysis of Finkelstein's albumin milk as published throughout the literature gives the following percentages

Fat	2.50 per cent
Albumin	3 00 per cent.
Sugar	1 50 per cent
Salts	0 50 per cent

It represents the fat and casein from 1 liter of full milk, casein, sugar and salts from ½ liter of buttermilk and water, ½ liter

Some have failed to add a half liter of diluent, and as a result there are only 32 ounces of a milk mixture as the finished product, which increases the percentage and caloric content quite materially The curds from 1 liter of sweet milk add about 250 c c or 8 ounces by volume to the liter of buttermilk and water, making 1,250 c c or roughly 40 ounces

Percentages vary in such a complex milk, the ingredients of which are obtained from so many different sources The fat, proteid and sugar content of both sweetmilk and buttermilk is not constant, while not always is the same amount of curd precipitated, due to variations in the pepsin, the temperature and the time Several analyses have been made for me by reliable chemists[1] The composition varies widely, which coincides with the findings of Birk[2]

The milk which I have used in the cases reported I have designated "high-percentage albumin milk" The analysis from one specimen gave

Fat	2 00 per cent
Protein	3 31 per cent
Carbohydrate	0 51 per cent
Ash	0 90 per cent

Other analyses did not give so high carbohydrate, but the fat has tested as high as 2 9 per cent and the protein 5 per cent Therefore, I have found it impossible to state a uniform percentage Likewise, the caloric estimation must vary somewhat, but the above analysis gives 18 3 calories per ounce, and 585 for 32 ounces This is an average caloric content for the different analyses that have been made The composition of high-percentage albumin milk is as follows Fat and casein from 1 quart full milk Casein, sugar and salts from 1 quart buttermilk No water added[3]

This formula, then, makes a total of 40 ounces, and is made up of a quart of churned artificial buttermilk made with a lactic acid ferment, reenforced by the addition of the precipitated fat and casein from a quart of sweet milk

The primary object was to obtain a milk that could be used in the transition from Finkelstein's formula or from buttermilk It has a higher salt-, sugar-, casein- and caloric-content than *Eiweiss-Milch*

Malt sugar, cane-sugar or flour have in certain cases been added in from 1 to 4 per cent This corresponds with the recent work[4] done by Finkelstein's pupils in Berlin

The infants to whom this mixture was fed and all of whom up to this time are reported herein were under 6 months of age at the time the feeding was begun, ranging from 22 days to 5½ months All were inmates since birth in the institution and had been continuously observed Many of them had not gained on breast-milk, and none of them had gained on sweet milk All of them had shown stationary weight, most of them had had undigested stools, and many had various degrees of atrophy

REPORT OF CASES

Case 1 —Baby Ar, weighing 3,920 gm at birth on Sept 14, 1911, had not regained birth weight at the end of two weeks when he had to be taken off the breast The next ten days showed a rapid fall in weight and dyspeptic stools while being fed a simple sweet milk dilution with sugar addition When the child was 24 days old he was put on Finkelstein's *Eiweiss Milch* for ten days, the stools were still somewhat green and undigested, the weight remaining stationary at 3,110 gm, which was 800 gm less than the birth weight At the age of 34 days the food was changed to the high percentage albumin milk The infant gained 830 gm in the next twenty six days Then followed a period of a month during half of which time sugars were added without any gain at all, the stools for the most of the time being macroscopically good.

---

* Read in the Section on Diseases of Children of the American Medical Association at the Sixty-Third Annual Session, held at Atlantic City June 1912.

[1] Analyses of buttermilk *Eiweiss Milch* and high percentage albumin milk have been made for me on different occasions by the Kansas City municipal la[illegible]tory a[illegible] the Kansas City testing laboratory

[2] Birk Monatschr [illegible] 140

[3] The technic of [illegible] loyed by Fink[illegible]

[4] Renfrey J[illegible] 12 The au[illegible] that the sugar add[illegible] 3 per c[illegible] go up to 6 7 or 8 [illegible]od

At the beginning of the infant's fourth month at first 1 per cent and later 2 per cent cane sugar was added, with a subsequent gain of 800 gm in the next twenty four days It was then thought that the child could safely be put on a sweet milk mixture, but he began to lose and to develop green stools Buttermilk with cane sugar caused a temporary slight gain, the temperature being normal but constipation marked February 24, when the child was 5 months old, the high percentage albumin milk without sugar addition was again begun and during the ensuing month the gain in weight was 1,000 gm, the stools and temperature being normal The child at this time left the institution in good health

CASE 2—Baby Wi, weighing 2,845 gm at birth on Sept 26 1911, nursed for two weeks at the end of which he weighed 3 005 gm, after which he was fed on various cow's milk formulas until November 21, maintaining a stationary weight From November 21 to December 3, he was fed Finkelstein's *Eiweiss Milch* with no gain The stools were somewhat constipated December 3, the infant was put on high percentage albumin milk, gaining about 500 gm in seven days The weight was then stationary for twelve days when 1 per cent cane sugar was added, the child gained slowly but constantly January 11, 2 per cent malt extract was substituted for the cane sugar, the weight increasing in the next twenty seven days from 3,865 to 4,705, nearly a kilogram, when the child left the institution The stools during this period were from one to four daily and of normal consistence usually, the temperature and general condition were good. Thus this infant was fed for two months on a high percentage albumin milk, gaining both before and after the addition of sugar for a total of 1,750 gm

CASE 3—Baby Ol, weighing 3,917 gm at birth on June 28 1911, nursed for twelve days with an initial loss of 400 gm at the twelfth day, he was then fed on various cow's milk mixtures until he was 5½ months old at which time he weighed only 3,740 gm The first four months of life the infant had frequently dyspeptic stools and showed marked atrophy A moderate gain on buttermilk with cereal addition occurred from the 4th to 5½ months, at which time was begun the high percentage albumin milk without sugar addition For the following three weeks there was a gain of 620 gm Then 1 5 per cent malt extract was added, the infant going from 4 280 gm to 5 700 gm in the following two months, the weight remaining here for two weeks when a change to malt soup was made During this time a double infantile glaucoma appeared, but the child continued to gain slowly

CASE 4—Baby Te, weighing 3,310 gm at birth on Oct 10, 1911, nursed for two weeks at the end of which time the weight was 400 gm below the birth weight. For the next two weeks the patient was fed on a simple sweet milk dilution and lost weight, had dyspeptic stools but a normal temperature During the second and third months of the child's life there was a slight gain on buttermilk with cane sugar, the stools remaining bad and the temperature normal At the age of 2½ months the food was changed to Finkelstein's *Eiweiss Milch* for two weeks with improvement in stools but none in weight Jan 11 1912, when the infant was 3 months old the high percentage albumin milk was begun The weight was only 3 387 gm Malt extract 1 per cent was added and the infant gained 700 gm in the next thirty days, the stools for the most of the time being in good condition

CASE 5—Baby Al, weighing at birth 2 720 gm on Oct 30 1911 was fed from the start on a sweet milk mixture with no initial loss of weight but at the end of the first month weighed 200 gm less than at birth The stools had been irregular, some days showing curds and constipation, but in good condition at the time of beginning high percentage albumin milk on the thirty sixth day of life There was an immediate gain of 300 gm in five days, after which the weight remained stationary and the stools and temperature normal No further attempt was made with this food.

CASE 6—Baby Har weighing 4 000 gm at birth on Oct 31 1911 nursed sixteen days was still 100 gm below initial weight continued to lose weight for the next three weeks on a sweet milk formula. Temperature was normal and stools

RESULTS OF FEEDING HIGH PERCENTAGE ALBUMIN MILK IN SIXTEEN INFANTS WITH STATIONARY WEIGHT AND VARIOUS DEGREES OF ATROPHY

Number	Name	Birth Weight Gm	Age (Days) at Time This Food Was Begun	Time (Days) on This Food	Weight (Gm) at Beginning	Weight at End	Total Gain	Carbohydrate		Stools Before Using	Stools During Using	Temperature	General Results	Outcome of Case
								Day When Added	Kind (Percentage)					
1	• Ar	3 020	34	75	3 120	6 210	3 090	34	Cane 1 5	Dyspep	Digest	Normal	Good	Left institution normal
2	Wi	2 845	67	68	3 045	4 705	1 750	10	Cane 1 5 later malt	Green mucus	Yellow digest	Normal	Good	Left institution normal
3	Ol	3 017	160	102	3 660	5 725	2 065	22	Malt 2	Good	Good	Normal	Good	Developed infantile glaucoma
4	Te	3 310	88	38	3 387	4 065	678	8	Malt 1	Loose green	Usually good	Normal	Good	Left institution normal
5	Al	2 720	37	15	2 615	2 970	355			Constip	Constip	Normal	Fair	Gained slowly on malt soup
6	Ha	4 000	50	22	4 052	4 400	348	5	Cane 1	Good	Digest	Normal	Fair	Gained slowly on malt soup
7	Sh	4 045	34	7	3 825	3 800	—25			Green	2 to 4 dyspep	Normal	Poor	Stools became normal when food was changed to malt soup

15	Le	3 560	27	43	3 398	4 315	917	7	Malt 4	Constip	Good	Normal	Good	Put on sweet milk
16	Gr	3 405	30	35	3 020	348	328	5	Malt 4	Dyspep	Good	Normal	Good	Continued good.

good December 6, weight was 3,030 gm, but a change to buttermilk caused a gain of 500 gm in 8 days, when weight remained stationary for a week High percentage albumin milk with 1 per cent cane sugar was then fed for ten days with a gain of nearly 500 gm, again a stationary weight for five days when a sweet milk formula was begun

Case 7—Baby Sh, large infant with stationary weight at 1 month of age was given high percentage albumin milk for one week without any gain During this period the infant had a nasal discharge, stools were somewhat dyspeptic, temperature between 99 and 100 F, which became normal by the time this food was stopped

Case 8—Baby Ha, aged 2½ months Feb 2, 1911, who has gained only 300 gm since birth, gained about 200 gm in the next twelve days on high percentage albumin milk, but remained stationary for the following eight days when dextri maltose was added Bowels became constipated but temperature was normal

Case 9—Baby Wa, aged 3 weeks, weight 3,795 gm, stools loose, green, but only two daily, was fed for eleven days on high percentage albumin milk with complete improvement in the stools, but a gain of only 200 gm in weight when 1 per cent cane sugar was added

Case 10—Baby Ma, aged 3½ months on March 31, 1911, weighed about 400 gm above birth weight, stools were usually loose and yellow There were evidences of moderate amount of malnutrition The child gained 400 gm in twelve days at which time he left the institution To this infant's food was added 3 per cent. malt extract The stools remained loose but good in color and frequency

Case 11—Baby Ca weighed at first month 2,530 gm, (5¾ pounds) no increase over the initial weight, although the infant was part of this time on the breast, the stools were dyspeptic and the temperature was usually subnormal He had showed a slight gain for two weeks previously on Finkelstein's formula with an occasional breast feeding A change to the high percentage formula without sugar caused no gain for the next week, but when malt extract was added a gain of 1,000 gm in the next month and one half was noted.

Case 12—Baby Wil, aged 53 days, weight 3,072 gm, had not gained since birth, there was marked constipation in spite of daily administration of olive oil, and the addition of dextri maltose to the milk Food was changed to high percentage albumin milk with from 2.5 to 5 per cent malt extract added the patient gaining 800 gm in the following twenty seven days, general condition was good

Case 13—Baby As, 1 month old, had been feed on various cow's milk mixtures with decreasing weight, with loose and undigested stools Weight at this time was 600 gm below birth weight From 1 month to 6 weeks of age, the high percentage albumin milk, with malt extract addition up to a total of 8 per cent, caused a marked improvement in stools, but a slight loss in weight Child continued to be atrophic

Case 14—Baby Da, 1 month old, stationary weight since birth, temperature normal, stools good, was fed for ten days on high percentage albumin milk with only slight gain, but maintained good stools

Case 15—Baby Le, weight at birth 3,560 gm on Feb 16, 1911, was fed from the start on a low fat and high sugar formula until twenty seven days old, with a slight loss in weight, when the high percentage albumin milk with 4 per cent of malt extract was begun The patient gained 800 gm in the next twenty eight days, the stools and tempera [illegible] ere normal

[illegible] 16—Baby Gr, 1 month old, had lost 400 gm since [illegible] l had dyspeptic stools When put on the high percentage [illegible] ilk with malt extract, 4 per cent., the patient gained [illegible] he next month, and continued to gain while in the

RESULTS

[illegible] igh percentage in this buttermilk mix- [illegible] using has been easily tolerated as [illegible] iformly good stools, frequent gain [illegible] of fever is hard to say, but the [illegible] creased digestibility from the presence of buttermilk and from the freedom of over-feeding by caloric control, while at the same time the infant is getting sufficient Heim and John, however, at Budapest, have recently reported good results from the use of a casein-enriched sweet milk[5]

Nine of the sixteen patients showed good gain in weight, a few of these being quite marked

Two showed loss and two only slight gain One of the former was the most atrophic in the series, In all of the cases the good effect on dyspeptic stools occurred Three infants remained constipated

As long as the infant continued to gain it was kept on this food Some gained with or without addition of sugar

3609 Baltimore Street

ABSTRACT OF DISCUSSION

Dr J H Hess, Chicago Unquestionably, catharsis gives us a great deal of aid in eliminating from the bowels, and, if proper cathartics are used, also from the kidneys, in all intoxications, especially those due to intestinal absorption I believe however, that there is danger of going too far I have never had the courage to give 6 grains of calomel to a young infant Not many months ago a series of experiments was carried on by Dr Abt in our clinic at Michael Reese Hospital to note the effect of the various cathartics in infants and young children We found in all infants that 1 grain of calomel given daily in divided doses over a period of three days produced at least microscopic blood in the stools The same thing was found when 1 dram of magnesium sulphate was given daily over a period of three days, and also but to a lesser degree when 1 dram of castor oil was given daily for three days Inasmuch as some of the patients were normal babies, sent to us for feeding because the mothers were sick, these findings were particularly striking I recall one well baby that was given 1 grain of calomel daily for two days It had no ailment of any kind, but we almost lost it It was several weeks before the baby was considered out of danger Undoubtedly, areas are opened in the intestinal tract, and infection takes place through them

I believe that one great trouble in this country is that most of us do not know how to make *Eiweiss Milch* Finkelstein did not give details for its preparation sufficient for use in the home or in the small clinic His was made by a large manufacturer with large equipment especially designed for a homogeneous mixture, and without these when making it in our clinic we do not get a fine curd As a consequence it does not go through the bottle, or we make an error in another direction and do not feed enough carbohydrate with it Since we have been making it according to later instructions our results have been entirely different When Dr Neff says that with the *Eiweiss Milch* he got no gain but with the higher percentage food he did, I think it was simply due to the fact that he did not follow Finklestein's dictum if you do not get a gain in weight add more malt sugar Dr Neff says that Finkelstein directs the addition of "one half liter of water and one half liter of buttermilk" What Finkelstein really says is "add one half liter of buttermilk and water to a full liter" So in my experience you only add about 6 ounces of water and not 16

Dr J L Morse, Boston We are now in a transition stage as to the question of etiology of diseases of the intestinal tract and therefore as to their classification The Germans are making at present a little too much of the chemical side We in Boston are perhaps thinking a little too much of the bacteriologic side, the truth may lie somewhere between I think almost everybody now feels that a baby from birth up even a premature baby, is able to digest a reasonable amount of starch, in many instances it is a great advantage to add it There is no reason to expect any harm to come from the addition of a reasonable amount of starch, whether dextrinized or not I read a paper last week on maltose in infant feeding in which I maintained that lactose was the best sugar for the normal baby It seems to me that one of the greatest things we owe to Finkelstein and his school is his calling attention to the injury sugar may do in the intestinal tracts of babies, especially milk sugar, and to the substitution of malt sugar for milk sugar in the later treatment When I speak of malt sugar, of course I mean the various preparations of dextrin and maltose, because nobody uses pure malt sugar A large number of intestinal disturbances in infants are due to the fermentation of sugar and its chemical action on the intestine These patients are relieved by cutting down the sugar to a minimum and feeding a high protein diet, but they improve more rapidly if malto dextrin mixtures are added instead of lactose I do not feel quite sure, from my experience whether precipitated casein as used in the *Eiweiss Milch* has any advantage over the straight casein I am sure that a high percentage of protein is of advantage We have to remember not only the chemistry but also the bacteriology of the intestinal tract Lactose is of advantage in some instances because it is slowly absorbed and maltose is of advantage in other cases because it is rapidly absorbed Then also lactose favors the growth of the *Bacillus bifidus*, a normal inhabitant of the lower intestine, while maltose favors the development of the *Bacillus acidophilus*, which may do harm In making Finkelstein's *Eiweiss Milch* it seems rather inconsistent carefully to take out lactose, which, if it does harm, presumably does so by the formation of lactic acid in the intestinal tract among other things, and then add buttermilk, which is full of lactic acid

---

[5] Heim P., and John K M. Ztschr f. Kinderh, Orig., March 1912 1 Series 4

We have found, in Boston, a certain number of cases which were undoubtedly meningismus, in which there was increase in the number of mononuclear cells in the spinal fluid, enough to lead to suspicion of tuberculous meningitis Subsequently, this was disproved It seems to me that a further knowledge is going to modify materially our judgment regarding the cellular findings in cerebrospinal fluid

Dr L T Royster Norfolk We should differentiate between the institutional case and that in private practice There are two main reasons why we have had a large number of deaths in institution practice first, lack of attention, I mean by that, insufficient help With ten bottle fed babies to one nurse, it is simply impossible to give them adequate attention The other is lack of ventilation and fresh air I have charge of a small institution for foundlings in my city, children who are abandoned from the slums of the city The children that have come into the institution have usually been doped to such an extent that a bowel movement is impossible for four or five days and they are practically starved We found that we were not doing quite enough in the matter of attention to these babies and we have our ward open all around to get as much fresh air as possible There is one graduate nurse in charge, and a student nurse from each of the two general hospitals and two ward helpers As nearly as possible I feel that that is giving the children just as good care as is possible in an institution Babies that are at all sick or young bottle fed babies are invariably held in the arms while they are nursed Personal care of each individual baby and plenty of fresh air are a great help

For the past winter in some select cases I have been using a preparation of malt sugar after a formula devised by Dr Leopold of New York I have obtained some interesting results from that I had two babies that were almost completely starved had almost complete obstipation, having been doped, and weighed almost nothing at 2 or 3 months They gained somewhat in weight, but did not reach normal, and stopped. The stools so far as I could see were normal, the baby was taking the requisite amount of food. The only change I made was to substitute dextrimaltose for whatever form of milk I was using One baby gained 11 ounces and the other 7 or 8 in the first week and kept up an average of 6 to 8 ounces a week for six weeks Then I took a small series of babies in a somewhat similar condition, as nearly as you can compare two or three babies and used them as an experiment, one was fed with one of the proprietary foods said to be especially rich in malt sugar, the second on milk-sugar and the other on dextrimaltose In that particular series the child on the proprietary food gained about 3 ounces a week, the child on the milk sugar gained about 5 to 6 ounces a week, and the child on malt sugar gained about 6 ounces a week I do not think it wise to keep the child on malt sugar indefinitely There comes a time when the child will stop gaining In many cases the slightest change in the child's food, even putting in a tiny little bit of starch, or as one investigator found, just a little condiment, would start a digestive improvement

Dr Herman Schwarz, New York It has been proved that the addition of malt sugar in a great many cases does help the children Finkelstein, if he has done anything, has shown the difference between the normal and the abnormal child as regards sugars, and that is one of the most important points we fail to recognize, that when we are talking of sugar preparations in infant feeding, we should distinguish between the normal and the abnormal child For abnormal children milk sugar is not the best. For the normal child it may possibly be all right I began about three years ago to use *Eiweiss Milch*, and it is used extensively in New York I wanted to find out whether it was the high protein, the absorption of sugar or simply the breaking up of the coagulum which caused fermentation I gave children *Eiweiss Milch* and then washed out the stomach, and the returned coagulum was about the same It seems to me that the results secured with *Eiweiss Milch* are due to the high percentage of protein It is not how much you give of any one component part of a food, but the combination I can give a child a high fat, providing I give a low sugar I can give a high sugar providing I give a low fat

Dr F S Southworth, New York The old idea that the child could not digest preparations of starch in its first year has been thoroughly cleared away by experimentation Many of us are in the habit of using the preparations of starch I do not think it is necessary as a routine measure, often using lime-water and plain water, but where there has been intestinal disturbance, children often do better on an admixture of a cereal diluent The original view taken of this matter was that the addition of the cereal diluent made a looser curd of the casein, and therefore made it more permeable by the gastric and intestinal juices, but it seems to me that there is another use for the polysaccharid carbohydrates We know that when Keller put out his "malt soup," he found that if he gave large quantities of the malt soup extract alone there was too much sugar and the child got diarrhea He was obliged to add starch to prevent this

It is my opinion that the starch when given acts to a certain extent in protecting against fatty acids as well as against the irritant effects of sugars, which is a further reason why I think the addition of cereal diluents helps us Of the three sugars, lactose saccharose and malt sugar, the lactose and saccharose are simply disaccharids, but the other which we use under the term "malt sugar" is really a combination of more or less of the two ingredients, maltose and dextrins We managed to get along for a good many years, disregarding the presence of these dextrins We made no particular study of their action Dextrin and starch have certain things in common Dextrin is apparently able to protect the intestine in very much the same way starch does The dextrin is capable of being further split up in the intestine into maltose If we give part of our sugar in the form of maltose and part in the form of dextrin, which is not fermentable or dialyzable and consequently not so readily absorbed and not so irritating, the latter can be slowly split in the intestine, and furnish further maltose during the time of its gradual absorption

Dr H Lowenburg, Philadelphia The papers bring up the subject of the relation of the laboratory worker to the physician I must confess that I am at times completely mystified by advice from the laboratory, it is so frequently contrary to clinical experience and contradicts itself About eight or nine years ago I heard a paper by a laboratory worker before the Section on the etiology of marasmus, in which the author said that the cure of marasmus consisted in finding the proper food I also remember another paper before this Section dealing with the etiology of summer diarrhea in which some very eminent authority described the etiologic factor as largely bacteriologic The Germans deny this For many years we were taught to look on the protein as the source of our trouble, and then the laboratory worker came along and told us it was not the protein but the fat and the sugar While I look to the laboratory for advice, I must confess that I have to be shown before I am willing to accept every new idea. In the last few years I have been feeding top milk mixture with cane sugar I see no reason to discontinue, my experience having been successful During June, July, August and September I pasteurize and try to get a mixture suitable to the child's digestion I believe that if we combine chemical and bacteriologic study in our search for a proper etiology of digestive troubles, we shall probably reach the correct solution of the whole problem I have never been able to understand why milk sugar should be the cause of so many digestive disturbances for which at the present time it is given credit, for the simple reason that it is a natural ingredient of human milk, in which it is present in a large amount The only reason I can advance is that the commercial product might be impure, contaminated with bacteriologic products, which are not properly destroyed by sterilization

Dr Roger H Dennett, New York Dr Schwarz spoke of having much better success with the malt soup than with the dextrimaltose I believe that that is because the malt soup requires superheating of the milk in its preparation It has been my experience, time after time, that some children cannot take milk that has not been superheated If you take them off the superheated milk they immediately develop intestinal indigestion

Dr Louis Fischer, New York I do not wish to be misunderstood that I ordered this dose of calomel for a child of a year I was talking about children in the Willard Hospital aged from 7 to 9 I am willing to admit that calomel might do harm I did say that the choice of active catharsis was left between magnesium sulphate, Rochelle salt and compound licorice powder In giving a dose of magnesium sulphate the house staff has a routine method of giving 2, 3 and sometimes 4 drams at one dose on admission, especially when there is a tendency to constipation In comparing a series of cases in the last ten years in which we allowed intestinal auto intoxication to occur we had more complications later in the disease I therefore wish to make one point we should have free elimination of the gastro intestinal tract, not necessarily with enormous doses of calomel or anything else, but with free stimulation of the emunctories of the body This would result in less complication, and perhaps shorten the duration of the disease

Dr. F C Neff, Kansas City Mo In answer to Dr Hess's question about the probability of some of the patients gaining if malt sugar had been added a complete analysis of the cases will be printed, in which I show how much sugar was added, and when Some did not gain at all until malt was added I had a few patients who did well without any sugar I wish to repeat that my object in presenting this series of cases was to show the results in feeding a milk which is undoubtedly indicated in certain patients, who are in certain degrees of atrophy The milder ones might be said to have a persistent stationary weight We had to find some food which was suitable. I believe some of these foods are better in these cases than the ordinary sweet milk mixtures I simply offer a suggestion for trial in certain cases in which other foods do not show a gain

---

Roast Beef and Hot Water in Exophthalmic Goiter—In my own experience, patients with pulmonary tuberculosis or intestinal tuberculosis do best on a diet consisting largely of raw or underdone broiled or roast beef and hot water, and I have found the same régime useful in many cases of Graves' disorder The hot water is sufficiently important to be emphasized by repetition Given regularly and in sufficient amount, i e, from 250 to 500 c c (*one or two tumblerfuls*) and preferably the larger quantity, about an hour before food four times daily, and between meals also, *ad libitum*, it keeps the gastro enteric tract clean and active, and it promotes elimination by the skin, the bowel and the kidneys Thus it permits a sufficient quantity of beef to be eaten, digested and assimilated, and causes the waste products to be excreted thoroughly —Cohen in *Am Jour Med Sc*

RELATION OF THE INFANT WELFARE MOVEMENT TO PEDIATRICS *

THOMAS B COOLEY, M D

DETROIT

We hear constantly nowadays that this is the era of preventive medicine, and the saying daily becomes more true The physician is ever more concerned with warding off the ills which once he aimed merely to palliate or cure As our science has grown, means have been made clear to us whereby the great scourges of humanity might be attacked at the root, and one by one they are being met and conquered Certain of these evils have been so wide-spread and so obvious that as soon as ways of mitigating them became apparent, the attack was readily converted into a popular movement or crusade of which there are several now in progress, the most conspicuous to day, perhaps, being the campaign against tuberculosis In all of these movements the medical profession has been naturally, of right and of necessity, at the head, as it must furnish the knowledge which guides all the work

THE INFANT WELFARE MOVEMENT

Curiously enough, one of the most fertile of all fields for the practice of preventive medicine has been left almost untouched until recently No single period of life is so fatal as infancy, no disease ever had so many victims Nothing probably causes more physical unfitness and wretchedness than the effects of infantile disease in those who survive Nothing is more appealing than the helpless baby — nothing more important to the world than this future man in the making No great discoveries were needed to show why infants die Yet the infant welfare movement is only now well under way The explanation of this may lie in the rather slow differentiation of pediatrics as a specialty So long as nobody devoted any special study to the baby, it was perhaps natural enough that the enormous mortality and morbidity of infancy should be considered an incident of that period of life, but it needed only the proof which our rapidly developing specialty soon furnished that this great sacrifice of life and health was not necessary, in order to start a campaign which, young as it is, bids fair in a few years far to outstrip in importance and popular interest any similar movement heretofore inaugurated Already, indeed, it is progressing so rapidly and being taken up everywhere so enthusiastically that it seems wise for us as pediatrists to consider just how it affects us and our specialty, and what our relations and attitude toward it should be

This infant welfare movement is of necessity a many-sided one, for the infant is threatened with perils from many directions In its fulness it involves other specialties than that of pediatrics and other vocations than that of medicine To give the infant his proper chance for life and health implies the study and practical application of eugenics the improvement of midwifery, the amelioration of poverty as it affects expectant and nursing mothers the bettering of housing conditions, and many other things which involve the activity of the sociologist, the lawmaker, the sanitarian and the practical philanthropist All of these things are of interest to the pediatrist also, as anything which affects the baby must be, and it is essential that he [illegible] ant with the needs and accomplishments [illegible] lines, but the greatest opportunity, the most promising of immediate results, lies directly in his own peculiar field. It has been clearly demonstrated by the efforts put forth within the last few years to cut down infant mortality that an overwhelming proportion of all the sickness and death among infants is due to nothing more than widespread ignorance concerning the feeding, care and hygiene of the baby, and that education of mothers and prospective mothers in these particulars can be successfully carried on in such a way as to bring about almost immediately a reduction of more than one-half in the infant death-rate among those reached. No more glittering opportunity was ever offered to preventive medicine than this, and no specialty ever had a better chance to show what it was capable of doing for the world. This particular phase of the movement, being so much the most immediately practical, is the one which is receiving at present altogether the most attention and being the most rapidly developed. It is almost always the first thing attempted when new work is undertaken in any community, and its success, when properly handled, is likely to be the stimulus to further endeavor along less obvious, but perhaps equally important lines.

TEACHING INFANT-FEEDING

The methods of carrying out this educational work are, or should be, familiar to all of us. The modern development of the *gouttes de lait*, the milk stations, the "mothers' clinics," or most descriptive term of all, the "prophylactic dispensaries," with their visiting nurses to demonstrate to the women in their homes how to carry out the instructions they have received, have been many times described. The "little mothers' classes" in schools and social settlements are a newer, but well-established development. The instructive literature distributed in many cities is no novelty. The only reason for dwelling on the relation of the pediatrist to these things lies in the fact that the movement is so popular, and the work seems so well developed and so simple that there is some danger of its getting out of hand and being attempted without the skilled direction which is essential to the best results. A certain amount of indifference on our part, combined with overzealousness and too great haste on the side of the lay philanthropist and the health authorities, might easily lead to an entire miscarriage of the work undertaken in any community, and we should have another such waste of money and effort as accompanied the work of many of the charities which confined their efforts to the distribution of clean milk of which so much was once expected, but which accomplished really little more than to help to prove that impure milk plays by no means the most important part in the causation of infant mortality.

It is the right and duty of the pediatrist to guide, direct and develop this educational work, and he cannot afford to delegate it to any one else. He is of course by no means the only one interested. Anything connected with the prevention of disease lies also within the province of the public health authorities, and at a time like the present when the scope of their activities is constantly and rapidly broadening, so conspicuous a movement as this is sure to attract their attention and invite their earnest cooperation, in fact there can be no question that eventually the department of child hygiene will be as much a matter of course in the public health work of any large city as the department of contagious diseases is to day. The danger, if any, is that this may come too soon. It is only natural that the enterprising health officer, whether from real enthusiasm or from desire to make a showing, should reach out after any such promising and popular cause as this, and endeavor to make it his own. Just when the time is ripe for this in any given city must depend largely on local conditions and on the character of the health officer. It is certainly impossible for any health office to do this work effectively until the public has been sufficiently educated to the need of it to be willing to support it properly. This education probably comes best through demonstration by well-organized private philanthropy. The most satisfactory development is perhaps the gradual assumption by the municipality of this private work.

There may perhaps be some question, according to one's conception of the proper sphere of municipal health work, as to whether the municipality should concern itself with the actual supervision of the babies, or limit itself to the dissemination of knowledge as to the dangers that beset the infant by means of literature and instruction in the schools, and to the collection of facts and statistics regarding infant mortality and its causes, and whether the prophylactic dispensaries would not more logically be connected with the children's hospitals or similar philanthropies. Municipal health work is developing so rapidly that this point could hardly be settled now, except by saying that it seems perfectly proper for any one to undertake work of this character who is in a position to carry it out satisfactorily. However all this may be, the prime essential for any enterprise of this character, municipal or otherwise, is good guidance, especially while the whole movement is still so largely in the formative stage. The municipality or the health officer who for political or any other reason gives this opportunity over into unskilled hands is hindering, not helping, the cause. To attempt wholesale teaching of infant-feeding and hygiene and have this teaching any but the latest and best would be a poor service to the community, and no one can determine just what is best and right to teach but the pediatrist who is fully abreast of the latest developments in his specialty.

Pediatrics is a real science and one which is making tremendous strides, especially in these very matters of feeding and hygiene. The best of the specialists have difficulty enough to analyze, assimilate and pass judgment on all the new work and the changing theories. The really competent pediatrists are none too common and the specialty is so new that it is still cumbered, in America at least, by a large proportion of self-styled specialists with no real training in this field, and no good reason for their title except an interest in babies. To leave the education of the public to any of this class would be worse than a mistake. Furthermore, those who have this work in charge are in a position to acquire information and collect evidence of the greatest importance to pediatrics, provided it is gathered by trained pediatrists. To give this chance into incompetent hands would be a lamentable waste of good material. The same arguments apply of course to enterprises conducted by private philanthropy.

It would seem needless to point out that such work cannot safely be left to the nurses alone, if it were not for the fact that this has actually been attempted. So much stress has been laid in all that has been written regarding the prophylactic dispensaries on the importance of the nurse's part that some enthusiasts have been misled into the supposition that she is the only essential. The nurse's position here is precisely the same as in private practice. She is the physician's invaluable assistant, and she must bear the brunt of the work, but to leave the whole thing to her would be simply to invite, on a large scale, the trouble which we all meet in private practice, when the sole responsibility for the baby's feeding and care has been assumed by the overconfident nurse It is a tendency to be guarded against rather than encouraged

The future of the infant welfare movement lies, then with the pediatrists It cannot be a real success without their cooperation and guidance, and in proportion as they give it their interest and influence promptly and freely will its healthy advance be rapid or slow In other hands than theirs it must not only lag behind the progress of pediatrics, but it runs the risk of falling short of promised results and being discredited

OPPORTUNITIES OF THE MOVEMENT

If the infant welfare movement is so dependent on the pediatrist for success, it cannot be said that it offers nothing in return Indeed, I think it may be said that it promises to be a most important agent in hastening pediatric progress First of all, it should do much toward giving the specialty the recognition and prominence which it deserves By giving wide-spread publicity to the unnecessary loss of infant life and the great need of skilled supervision of every baby, sick or well, and by its demonstrations of what can be done in this way for the children of the poor, it must considerably expand the scope of private pediatric practice and develop a branch of it which is now little enough in evidence "Welfare work" among the babies of the well-to do is as legitimate a part of our special field as the treatment of disease, and is really needed If these babies could be under the same constant, careful observation by competent pediatrists which we insist on for those of the poor in our prophylactic dispensaries, it would redound greatly to their advantage and our credit

In addition to broadening the field of ordinary pediatric practice, the infant welfare movement is opening up a special branch of pediatrics Every pediatrist should be acquainted with the general features and tendencies of the movement, but the men who are to direct it in the larger cities, who must of course be pediatrists first of all, and of the best, ought also to have a thorough special knowledge of all the branches and phases of infant welfare work as it is carried on not only in America but also in those continental countries where it was developed earlier and has been more thoroughly elaborated and systematized It seems quite evident that there will soon be a considerable demand for men who by such training are capable of directing work on a large scale

Another thing which we may expect from this movement is that it will emphasize the need of better teaching of pediatrics in this country, and of more opportunity for special study It is no secret that our general practitioners and many of our so called specialists are deplorably ignorant of pediatrics, especially of that most important part of it, the management of the young baby, and most of our schools offer at present no great opportunity to learn it Clinics and hospitals for the sick child afford no chance to acquire the necessary knowledge of the handling of the well baby so as to keep it well The infant welfare movement promises not only to call attention to this need, but also to afford a great chance to correct it by the opportunities afforded in the prophylactic dispensaries for the observation of normal children Instruction in the management of breast-feeding, which is perhaps more urgently needed than any other, can probably be given better there than elsewhere

With the bottle-fed baby the prophylactic dispensary gives us the best opportunity we have ever had to demonstrate what we have so long been preaching — the advantage of simple milk mixtures over complicated formulas and popular proprietary foods, and the utter needlessness of nearly all these To put the proprietary foods in their proper place is a thing I am sure we have all desired, and good management of our educational campaign should accomplish it Unskilful management, on the other hand might have as much the opposite effect as does unskilful feeding in private practice

We have also in this supervision of the feeding of large numbers of comparatively normal children an unusual opportunity to try out various feeding methods, such as one would hardly get in hospital or private practice In the large cities, the prophylactic dispensaries under one management have charge of the feeding of thousands of babies and this is usually carried out so far as possible according to a uniform method Regular observations and weighings are made and good records are or should be, kept Such careful compilations of these records as might be made by scientific directors would furnish invaluable material for comparative study of the results of different methods and might well contribute greatly to progress in infant-feeding

The prophylactic dispensary is by no means the only phase of the infant welfare movement which is of value to pediatrics The whole movement involves an intensive study of the causes, immediate and remote, of infant mortality and morbidity, which must not only add considerably to our pediatric knowledge, but must broaden our conception of pediatrics As it develops, it will give the would-be pediatrist constantly more to learn and make the real pediatrist a fuller man The tendency of the movement to bring pediatrics into closer touch with all the other specialties and interests concerned in any way with the baby must add fully as much to our knowledge of our subject and be as valuable an incentive to further study and better work on our part as on theirs, and should be welcome to all of us

SUMMARY

To summarize briefly the points I have tried to make

The mitigation of the present enormous mortality and morbidity among infants is the most promising field now open to preventive medicine and the infant welfare movement bids fair to become soon the most important of all the wide-spread popular campaigns against disease and its causes

The whole movement, though it involves many other specialties and vocations than pediatrics, must be of interest to the pediatrist and should be closely followed by him Its most important phase, however, is directly in his own field The greatest chance to reduce infant mortality has been shown to lie in educating the public, the mothers and young girls in infant-feeding and hygiene This work it is the right and duty of the pediatrist to direct and it cannot meet with its full measure of success unless under skilled direction Whether it be carried on in connection with the health office or the [illegible] independent private philanthropy, th[illegible] the thoroughly competent pediatrist [illegible] ep it from [illegible] rong There [illegible] ng lost sigh

The movement offers much to pediatrists It promises to give the specialty better recognition and to enlarge its field by calling attention to the need of skilled supervision of all babies

It will demand better teaching of pediatrics

It offers the pediatrist the chance to demonstrate on a large scale the possibilities of breast-feeding, and when this fails, of simple bottle-feeding without resort to proprietary foods

It gives an unusual opportunity to try out methods of artificial feeding with the normal child

It is stimulating a close study of the causes of infant mortality and morbidity which must add much to pediatric knowledge

It tends to bring the pediatrist into close association with all others concerned with the welfare of the infant, to his benefit as well as theirs

Finally, it might well be said that the whole infant welfare movement is nothing but the newer and broader form of pediatrics, and should be so considered Pediatrics, by the nature of the material with which it deals, is better situated than any other specialty for the practice of preventive medicine, and it is at the beginning of life that the systematic application of prophylactic measures can accomplish most and be of the greatest value We must not neglect our opportunity Individual pediatrists are taking prominent parts in the movement in many of the cities now, but considering the relative importance of their mutual relations with the movement, the representation of pediatrists in the organizations which are endeavoring to control and guide it is disproportionately small, and there is, so far as I know, no participation by any organization of pediatrists This condition should not continue It would seem only natural that every association of pediatrists should be sufficiently alive to the importance of the situation to be formally represented in the National Association for the Study and Prevention of Infant Mortality, and to take a part in its work, as well as in local enterprises, which should lay more emphasis on pediatrics and its essential relation to infant welfare As it is at present there is in this country no evident connection between two developments which should be inseparable — the growth of pediatrics and the infant welfare movement.

ABSTRACT OF DISCUSSION

Dr Charles Douglas, Detroit The pediatrist is the only one who is capable of directing the public on this subject in straightforward lines of truth that will not require to be reversed in two or three years from this time, which is likely to occur if the progress is from any other source than the pediatrist

Dr G R Pisek, New York Having been very actively interested in the campaign in New York last winter, I feel that this type of work should not be put into the hands of the health boards of the city too prematurely Not that they are not the ones to take care of it—logically they are—but we should previously have the work mapped out and organized so that they need only to follow it up and not to develop it Well directed philanthropy along these lines is the proper method of procedure The private organization can show the special need to the city authorities, and then finally help secure an appropriation from the municipality so that the health board can continue the work, and not only keep up the standards set for them, but advance them I think if that can be done in our cities on a large scale we shall have effective reduction in infant mortality To do infant welfare work in a small way in a large city is almost a waste We must have something definite to show at the end of the year, something to prove that we have modified infant mortality

Dr H K Hill, Philadelphia The physicians of Philadelphia, principally the pediatrists, presented last week what was called a "baby saving show" in Horticultural Hall, open for ten days, which was directed toward educating the public There were 17,000 in attendance in one day Four subsidiary shows were also held in the poorest districts of the city, the first one in a slum district at Third and Catherine streets There was an attendance of 23,000 in four days This movement has been so far very successful There were special exhibits from the government and from charitable organizations covering eugenics, the care of the baby, a miniature milk show—things which suggest themselves in working among the ignorant of the large cities

Dr Collins H Johnston, Grand Rapids, Mich We had a campaign of this kind last summer in Grand Rapids, a city of about 125,000 people, and accomplished a great deal It was conducted by the authorities of the Blodgett Home for Children Four or five of the medical men were interested in it and conducted a clinic once a week for babies We secured from the health office the name of every baby born in the city during the previous year and sent literature to the families At the end of a year we found that the infant mortality in the city had been reduced 55 per cent. below that of the year before, which, we think, was a very marked showing for the work done We do not know that it was entirely due to our efforts, as infant mortality varies from year to year For instance, Dr Neff has told me that last year was a good one for babies in Philadelphia, but that the year before was a bad one We do know, however, that our work did a great deal of good

Dr LeGrand Kerr, Brooklyn We as pediatrists must recognize the fact that as a class we are not yet very highly appreciated It is only within the last few weeks that the New York State Society has recognized pediatrists The general tendency is to make them subservient to the obstetrician As a specialty pediatry is not yet generally recognized as it should be If that is true in the profession, it is more emphasized outside, and it does not need much to have the health officer or health boards criticize the work of any of us who may interfere with their particular line of work, or who are not enthusiastic about the particular way in which they carry it out Dr Cooley has rightly emphasized the point that this question should not be relinquished readily to health boards or health officers, but should be under the direct and complete control, for a time at least, of pediatrists, until others are equipped to take up the work. Yet in another portion of his paper, Dr Cooley states that there are too few pediatrists who are well equipped for this work I do not agree with him By such a statement we place in the hands of those who are not in sympathy with the stand we take a tremendous power for dealing us a blow in having this work carried on If the pediatrists are to be recognized by the profession at large, by the public and by the health officers, they must stick together

Mr. William A Howe, Albany, N Y We in New York believe that you who are doing special work in this line are the ones who should assist us in a concerted effort to reduce the alarming infant mortality so extensively prevalent in every community With that idea in mind, Commissioner Porter has recently appointed on his consultant staff, one of the leading pediatricians of the state He is expected to advise and direct our department in public health matters pertaining to children As soon as appointed, he prepared a booklet on 'How to Save the Babies" This deals with the mother before the baby comes, with the mother and the child when the baby comes, and with the mother and the child after the baby comes It is brief, yet sufficiently comprehensive to teach the expectant mother, as well as the mother, much of practical value to her not only in preparation for motherhood, but in the care of her child and herself This little book we hope to be able to place in the hands of every expectant mother in the state or every new mother, as quickly as possible before the birth of her child or after its delivery Its distribution will be made through the local health officer, physicians and registrar, or any person desiring can apply for a copy direct to the Commissioner of Health Many thousands of copies have been circulated and we regard it as one of the most popular and practical movements of the department in educational work

Health departments need and must have your cooperation as specialists With it they can accomplish much more than would otherwise be possible, and is not the same equally true so far as you are concerned? While you are assisting us can we not frequently reciprocate? Does not reciprocity in public health work offer one of the greatest opportunities for accomplishing good, and should not physicians and sanitarians be its strongest advocates? I want to appeal to you to cooperate with your local health authorities along these lines and not, as stated by Dr Kerr, attempt to assume the full responsibility or the full activity in this important public health question, which is one of the greatest with which we are concerned and one capable of the greatest possibilities

Dr H M McClanahan, Omaha There is one statement, which if I heard aright, I think ought not to go unchallenged that the chief result of the milk propaganda had been to indicate that milk was of much less importance in relation to the infant mortality than we had formerly supposed This is a surprising statement to come from a man who has shown so much familiarity with infant welfare, as Dr Cooley In fact a considerable portion of the rest of his paper largely nullified that statement How is one going to feed these babies right if he does not start with good, clean milk? Most of the men in this room would agree that one of the most important things in the promotion of this infant welfare movement has been derived from pure milk movements, beginning with the certified milk movement and other influences that go to the improvement of a pure milk supply I believe that Dr Cooley will agree with me that that sentence was inadvertent, and should not be published

Mr W A Howe, Albany, N Y Inasmuch as several members of your Section have expressed a wish for a copy of the little booklet on "How to Save the Babies" to which I referred, I might add that Commissioner Porter will be pleased to send a copy of the same to any physician present who may designate his desire by writing for it

Dr T L Harrington, Milwaukee, Wis This is a new line of work, and as a result some mistakes will be made It will be interesting for the members present to know the experience we have had in Milwaukee Some time ago the county medical society started work along this line Shortly after the advent of the social workers among the poor, a movement was started to bring to the city a social worker to take charge of child welfare work This work was started in August, 1911, and, under the advice of a committee of physicians, has proved effective and successful In less than a year the death rate among infants in a portion of the Polish district in Milwaukee was reduced 60 per cent This social worker when not a physician is necessarily under the advice and guidance of physicians A nurse was sent into every home in which it was reported that a baby had been born The columns of the newspapers of the city were thrown open to the child welfare movement, and a short column on child welfare was printed in every newspaper in the city six days in the week These articles were furnished by the child welfare commission

It seems to me that this is a work of tremendous importance At present the work has been taken over by the health department The social worker who was at the head has another position, and a physician is to be put in charge I believe that a physician should be at the head of this work for several reasons It is not only necessary that he should be a trained pediatrist, but also that he should have a training in social work It is extremely important that the physician who is the guide in this work should have had some sociologic training If he is not a student of sociologic conditions he is not going to make a success of this work

Dr John Zahorsky, St Louis I want to point out certain weaknesses of the movement The first is that pediatrists are not agreed on certain things, especially in connection with feeding There are general hygienic principles, however, which can be carried out. Second, it will not do to put the work in the hands of pediatrists who are not properly trained in this line of work, because the confidence of the people is gradually lost The work should go slowly, I think.

Dr T B Cooley, Detroit In answer to Dr Kerr, I know that I did not say that pediatrists are none too good, but that they are none too common As to the effect it might have to have such statements go out in the first place this paper was written for pediatrists In the second place, some of those instances have already arisen, and it seems to me that the best place to mention them is before a group of pediatrists

Perhaps I made the statement regarding milk philanthropies a little too bold, but it is true that philanthropies which do nothing but furnish pure milk do nothing to reduce infant mortality Some have developed into useful philanthropies, because they found they had been accomplishing nothing, and have gone into welfare work

THE PROPERTIES, USES AND INDICATIONS OF THE VARIOUS CARBOHYDRATES USED IN INFANT-FEEDING *

HENRY DWIGHT CHAPIN, M D

NEW YORK

In infant feeding the term "carbohydrate" is applied to a number of compounds related to starch and sugar, which contain carbon united chemically with hydrogen and oxygen, these elements being present in the proportions of two parts of hydrogen to one of oxygen, as in water, H_2O

Many carbohydrates are known and their common ultimate chemical composition is shown in Table 1, covering carbohydrates employed in nutrition work

TABLE 1—CHEMICAL COMPOSITION OF CARBOHYDRATES USED IN NUTRITION

Carbohydrate	Composition Carbon	 Hydrogen	 Oxygen	Formulas
Cellulose	6	10	5	$C_6(H_2O)_5$
Starch	6	10	5	$C_6(H_2O)_5$
Dextrin	6	10	5	$C_6(H_2O)_5$
Glycogen	6	10	5	$C_6(H_2O)_5$
Cane sugar (saccharose)	12	22	11	$C_{12}(H_2O)_{11}$
Milk sugar (lactose)	12	22	11	$C_{12}(H_2O)_{11}$
Maltose	12	22	11	$C_{12}(H_2O)_{11}$
Dextrose (synonyms diabetic sugar glucose grape sugar)	6	12	6	$C_6(H_2O)_6$

The carbohydrates are used in nutrition for the energy and water they yield on oxidation As the hydrogen will be satisfied by the oxygen in the compound, all there remains to be oxidized is the carbon The number of calories a carbohydrate will yield depends, therefore, on its carbon content

It will also be noticed that the only difference in composition among the various carbohydrates, as shown in the table, is in the amount of water (H_2O) combined with the carbon

When carbon and oxygen combine, energy and heat are liberated, and as the fate of carbohydrates in nutrition is to be combined with oxygen of the air taken in by the lungs, it is evident that carbohydrates are used to supply energy and heat to the body and are properly classed as energy foods

The amount of energy a material can supply may be determined directly from the amount of heat evolved when it is burned with oxygen, and it is customary to judge the value of energy foods by the number of calories or heat units a given weight of the food will yield when burned

---

* Read in the Section on Diseases of Children of the American Medical Association at the Sixty-Third Annual Session held at Atlantic City, June 1912.

As there is not much difference among the various carbohydrates in carbon content, and as the hydrogen and oxygen satisfy each other, there is little difference among them in the number of calories they will yield, and in practical nutrition work all carbohydrates are assumed to be interchangeable as far as caloric value is concerned

All carbohydrates used in nutrition have the same nutritive function and about the same caloric value, but they differ in physical properties (some, as starch and glycogen, being insoluble), in the amount of digestive effort they call forth, in the rate of assimilation, and in fermentability

Care must be exercised not to judge the availability of a carbohydrate for infant-feeding from its most obvious properties, or decidedly erroneous conclusions may be drawn For instance, cane-sugar is not directly fermentable, but it is apt to cause fermentation, milk-sugar is not fermentable by pure yeast, but there are times when it cannot be used, because of fermentations Maltose, on the contrary, is exceedingly fermentable, being used in preference to other carbohydrates in the fermentation industries, such as the manufacture of beer, yet it is used most successfully in infant-feeding and is especially recommended in cases of intestinal fermentation One of the grand contradictions of nutrition is that the more fermentable a carbohydrate is, the better fitted it is for use when poor digestion and assimilation of carbohydrates are present

To understand the indications for the various carbohydrates in infant-feeding it is necessary to follow them from the time they are ingested until utilized and excreted

ASSIMILATION OF CARBOHYDRATES

No matter what form of carbohydrate is taken, if it can be digested it is ultimately changed into dextrose before utilization and carried to the liver where it is converted into insoluble glycogen and stored for future use If the absorption of dextrose or other carbohydrate is too rapid, the liver cannot convert it into glycogen as fast as it is presented and the excess passes into the urine with resulting alimentary glycosuria There seems to be some regulative apparatus which prevents the blood containing more than a certain amount of sugar When the amount of carbohydrates assimilated is greater than is needed to maintain the supply of glycogen in the liver, it is converted into fat, which is a more concentrated energy food than glycogen, having a little more than twice the caloric value, the relative values being 28 to 12

A small amount of glycogen is found in all the cellular tissues and in the muscles, even in embryos If there is a demand for energy, as when a muscle contracts or the heart beats, the glycogen of the tissues or muscles is converted into dextrin, maltose and dextrose successively, the carbon of the dextrose is then oxidized and the energy is liberated, heat being produced at the same time The carbon dioxid produced is excreted by the lungs and the heat passes off by radiation or is converted into latent heat by the evaporation of perspiration, depending on the temperature of the air

The performance of work rapidly depletes the supply of glycogen in the muscles, and that in the liver is called on to make good the loss Glycogen is so nearly like starch that it is called animal starch Both are insoluble and both are acted on by diastatic ferments forming dextrin and maltose, which are converted into dextrose, the sugar found constantly in the blood When the glycogen of the muscles is used up during work the enzymes of the liver and blood convert the glycogen of the liver into dextrose, which the blood carries to the muscles where it is reconverted into glycogen This continues as long as there is glycogen in the liver When the supply of glycogen in the liver is exhausted, the fat is converted into dextrose and carried to the muscles and changed into glycogen As is shown by studies in metabolism of starvation, the expenditure of energy depends on the presence of glycogen in the muscles, and for this reason glycogen is found in the muscles long after the supply in the liver has been exhausted and to the end of starvation

PHYSIOLOGIC PROPERTIES

When it is thoroughly understood that the final product to be produced from the carbohydrates taken as food is glycogen, the order of availability of the various carbohydrates will readily be grasped from the following outline of their physiologic properties

1 Only fermentable sugars form glycogen

2 Dextrose and maltose when injected subcutaneously are assimilated because the blood contains enzymes that will convert dextrin and maltose into dextrose Dextrose and maltose are highly fermentable

3 Cane-sugar and milk-sugar when injected subcutaneously reappear almost entirely in the urine because they are foreign to the blood and cannot produce glycogen until they have been converted into fermentable sugars in the intestines

4 The relative order in which sugars are available for forming glycogen is *dextrose, maltose, cane-sugar, milk-sugar*

While dextrose has the highest limit of assimilation, too much of it in the food will overtax the liver and cause alimentary glycosuria, as it cannot be converted into glycogen as fast as it is absorbed

A certain amount of energy is expended in digesting and assimilating carbohydrates, and *their relative food value* depends on the amount of energy that must be expended in converting them into dextrose The reason maltose and cane sugar have greater availability than milk sugar is shown by the following illustrations of what takes place when they are rendered assimilable

$$\text{Maltose} + H_2O = \text{dextrose} + \text{dextrose}$$
$$\text{Cane sugar} + H_2O = \text{dextrose} + \text{levulose}$$
$$\text{Milk sugar} + H_2O = \text{dextrose} + \text{galactose}$$

Maltose is completely converted into dextrose by the chemical addition of water and is immediately available, cane sugar when split up is converted half into dextrose and the other half into levulose, which the enzymes of the blood can convert into dextrose, while milk-sugar is converted into half dextrose and half galactose, which must undergo further change before it can be assimilated The net energy value of maltose is greater than that of cane sugar, and the net energy value of cane-sugar is greater than that of milk-sugar

The tendency for fat to be stored after the liver is filled to its capacity with glycogen readily explains why maltose and cane sugar, which have a higher net energy value, are more apt to cause fattening than milk-sugar, and why a high maltose content in the food is prone to cause diarrhea — it is crowding the liver too much and must be eliminated

ADAPTATION OF CARBOHYDRATE TO INFANT'S CONDITION

When an infant is strong and vigorous it has a plentiful supply of glycogen in its tissues and liver, and therefore a reserve of energy Under these conditions milk-sugar, which is slowest to produce glycogen, acts well, as it does not overtax the liver or cause alimentary glycosuria or excessive fat production When an infant is weak or poorly nourished and its reserve of energy is small, there is a demand for rapid production of glycogen For such infants dextrose or maltose, which can be taken directly into the blood and converted at once into glycogen in the tissues or muscles, where there is a demand for it, are more effective than milk-sugar or cane-sugar Maltose is particularly available because it is one of the forms through which all the carbohydrates of the body pass before they are utilized When absorbed, maltose can be changed into glycogen in the tissues or into glycogen in the liver as conditions warrant It might be said to turn either to the right or to the left as its presence is needed in either direction

In this connection it is significant that in the process of adult digestion the first product of the digestive secretions is maltose from the starches by the action of the saliva Since we know that there is a large expenditure of energy during the digestion of a meal, it is fair to infer that Nature intended this energy to come from the food that was being digested and not from energy stored up from a previous meal, and thus provided that the maltose should come from the food and not from the glycogen of the liver At any rate, it is well established that thorough chewing of a mixed diet renders digestion easier than if the food is bolted

There can be no question but that by adding products of starch digestion, such as dextrin and maltose, to an infant's food, the same digestive effect is produced as when an adult thoroughly mixes his food with saliva, and that the energy needed for digesting the food can be obtained from the food itself This may be of advantage when the infant is called on to digest cow's milk, which requires the expenditure of more energy than does human milk, or when the infant is poorly nourished and therefore has no appreciable reserve of energy in the form of glycogen

In the artificial feeding of infants there are more factors to be considered than the composition of the food and its caloric value, for it has been shown that all carbohydrates have practically the same caloric value, but that they are not equally available, different amounts of energy being called for to render them suitable for assimilation While it is possible to determine the energy required to render assimilable the food of individual animals experimented on, no law or rule can be established that will apply to all infants, because of individual differences

A point that should not be overlooked is that the physical condition of the food has a marked effect on its nutritional value even if it is completely digested Animal experiments have shown that from 40 to more than 100 per cent of the energy or caloric value of a meal may be expended in digesting it, and Armsby has pointed out that on certain forms of food an animal will die of starvation sooner than if no food at all were eaten, the explanation being that all the energy of the meal and a considerable portion of the stored-up energy are expended in the work of digesting the food

When infants are fed cow's milk the problem of energy expenditure in digestion is necessarily different from what it is when human milk is given, because of the differences in the physical properties of the milks after being clotted by the gastric secretion Clinical experience the world over has shown the advantage of having part of the carbohydrates of the food in quickly assimilable forms

For nearly twenty years I have practiced and taught this truth,[1] and Keller and Finkelstein have also strongly advocated an application of the same principle though in a different manner

All have recognized the necessity of altering the physical properties of the curd of cow's milk in some way, and the addition of alkalies, decalcifiers or antacids for doing this by chemical means or the use of gruels for accomplishing the same thing by mechanical means is almost universally practiced Finkelstein clots the milk and then passes it through a sieve to obtain the same effect

All these methods of modifying the character of the curd of milk lessen the demand for energy during digestion When easily assimilated carbohydrates are added to the food so prepared, energy food is made immediately available and the net value of the feeding is increased

A SCHEME OF INDICATIONS

Conditions so vary with individual infants that I have always believed that the best method of preparing substitute food for them is to use as a basis milk or top milk diluted with cereal gruels of definite strength for the mechanical effect on the curd of the milk, and then by altering the character of the carbohydrates adapt them to the energy and digestive requirements of the individual infant As glycogen and starch are essentially the same and undergo the same chemical transformations when acted on by diastase, it becomes a simple matter in practice to prepare food in the home that shall call forth all the digestive powers when there is plenty of reserve energy in the infant, and for infants whose reserve of energy is small, a slight change in the method of preparation of the food will alter the availability of the carbohydrates in such a way that the infants will be supplied with such materials as they would prepare in their tissues if they were normal

These methods are simple, inexpensive and almost universally applicable, but they must be applied with an understanding of the purposes various carbohydrates serve in nutrition They consist essentially in using gruels made from various cereals as a starting-point and then by means of diastase converting the starch into soluble starch, dextrin or maltose as may be required The extent of the conversion of the starch is to be regulated by the digestive ability and needs of the infant A nearly complete conversion into maltose is indicated when rapid assimilation is desired To obtain the maximum amount of maltose the conversion should take place at about 150 F, but when soluble starch and dextrins are sought the temperature should be about 165 F

51 West Fifty First Street

ABSTRACT OF DISCUSSION

Dr Charles Douglas, Detroit It has been my experience that these children will digest so much curd, irrespective of the addition of the carbohydrate I have used them both ways, and have been very much impressed with the fact that this subject has received greater prominence than it has deserved I have watched the effect of increasing the amount of each one alone, and have not been convinced that it is of such great value as is commonly thought I do not wish to deny that it is beneficial, but I think it is overestimated

The idea presented by the paper regarding the digestibility or the advantages of digesting starch in different ways brings up very strongly the question of the addition of starch to the dietary in the dry form at as early a date as it is possible to get the child to take it This brings us back to the old so called errors which we have been inclined to attribute to mothers when feeding their infants while nursing, giving them always a little taste of bread or cracker or something else from their own food We are compelled to recognize the fact that these women have been doing a great deal of good as well as some harm, but there is no doubt of the fact that the giving of the starch in this dry form has a very great advantage over the giving of it in a wet form This occurs continually in all our work, and I have been so impressed with it that for years I have taught mothers to give a piece of crust just as soon as the child nibbles at it And as rapidly as the child will take the dry starch to reduce the wet form, I have made this a routine practice

[1] Studies in Infant Feeding New York Med Jour Sept 16 1893

Dr J P Crozer Griffith, Philadelphia I do not think that Dr Chapin means to exclude the older plan of treatment the employment of milk sugar There is too great a tendency to day to the abandonment of this in feeding infants, and toward the using only of malted preparations It is a pity, perhaps, that we medical men tend so much to run to extremes There is just now a wave of maltose feeding It has gone over the country in the last year or two, and over other countries as well I have for years been a great believer in the use of dextrinized starch in certain cases in infant feeding I have long used it, and have obtained excellent results, dextrinizing the starch in the nursery as required But even before that I had excellent results, as we all have had, with food containing no dextrose or maltose but sugar of milk The matter is an individual one with the infant The average healthy infant does not need dextrinized starch, but there are many cases in which it fills a very useful place

Dr H D Chapin, New York The different elements of milk have assumed great importance in the professional mind at various periods We remember years ago it was all fat, then all casein and curd, and, in the recent year or so, all sugar My idea in preparing this paper was simply to clarify our ideas with reference to sugar in the food, how we could utilize it, and when the different sugars should be used I did not mean in any way to recommend that these other sugars should take the routine place of milk sugar In fact, the whole paper was merely intended to show how milk sugar is normally assimilated under ordinary conditions, and also to show how and when these other sugars could become available and temporarily displace milk sugar We must have in our hands the knowledge and a method of utilizing these different varieties of sugar for specific cases I do not usually recommend dextrose for ordinary cases

THE PRACTICAL IMPORT OF RECENT WORK ON HYSTERIA *

TOM A WILLIAMS, M B, C M, (EDIN)
Corresponding Member of the Societies of Neurology and Psychology of Paris Neurologist to Epiphany Dispensary
WASHINGTON, D C

Whether hysteria is determined, as Breuer[1] thinks, by the occurrence of peculiar dream-like conscious states with a narrowed association capacity, and whether these are purely due to psychically painful experiences as argued by Freud,[2] or whether, following Janet,[3] hysteria is to be summed up as a weakness of the power of associating impressions, or whether it is an actual splitting of consciousness which more or less divides its victims into the exaggeration of many-sidedness known as multiple personality (Sidis[4]), or whether, with Sollier,[5] we conceive hysteria as an inopportune sleep or numbness of a part of the cerebrum, all clinicians agree with Babinski[6] that the most conspicuous and invariable characteristic of a hysterical patient is suggestibility

As nothing is more detrimental to the progress of science than to call by the same name phenomena which differ in essence, it would be eminently desirable that students of the psychoneuroses should adopt some least common measure for the study of each group, and as it seems quite evident that there is a group of various symptoms, each of which is "susceptible of being produced by suggestion and removed by suggestion-persuasion,"[7] it is strongly to be desired that differences should be sunk for the time being in order that by use of a common, unique and unequivocal character we may collect examples by the correlation of which we may hope to penetrate more deeply into the origin of pithiatism[8]

That Babinski has fallen back on a teleologic definition[9] of suggestion is to be deplored, for the sense in which he uses the word, that of an insinuation, that is, something evil, is entirely subversive of the essential psychologic mechanism that is connoted by it, and so long ago made clear by Bernheim[10] The essence of implantation of ideas by suggestion is not their evil nature but the manner of their reception the subject receives them unaware of how they have gained entrance to the mind

Elsewhere[11] I have tried to develop the difference between this process and that which may be called persuasion, in which the subject takes full cognizance of the manner in which his belief is caused to alter A man persuaded knows why he knows a person who has received ideas by suggestion merely knows It is the method in which knowledge is acquired by children, savages, many of the uninstructed and the credulous in general Examples will make clear the manner in which symptoms are acquired by suggestion

Case 2 —*Hysterical Obsession and Phobia* —After an attack of influenza, a woman returning in a crowded car from a shopping expedition began to feel much oppressed and in want of air The heart, enfeebled by the influenza poison, and we know not what others taken as medicaments and aliments, ceased to respond to the call on it for a more rapid flow of blood so that the aeration could be sufficient and a faint ensued, with the psychic accompaniments of irresistible terror and dread of dissolution Never since has this woman been able to bring herself to go alone into a car, the very idea of doing so induces the fear of fainting She is not obsessed by the idea so long as the question of entering a car does not arise, but although she knows her conduct to be unreasonable, she cannot bring herself to act reasonably about going alone into a car

The suggestibility of children[12] is much more labile than that of adults, for while they are very susceptible, children do not usually hold tenaciously and are easily diverted from their loosely fixed ideas when morbid For instance, it is perhaps unique for a girl so young as 11 to believe that she is utterly unable to eat, and to believe that strongly enough and long enough to overcome the instinct of hunger to such an extent that she had to be removed for treatment to a hospital, in the Salle Pinel of the Salpêtrière, Professor Déjerine built up her emaciated body by generous feeding, and at the same time undid the false notion she had acquired from her elder sister who had been a patient in the same place[15]

The cases under the heading of "Treatment," show the mechanism also

THE ALLEGED TROPHIC SYMPTOMS OF HYSTERIA HYPERTHYROIDISM EMOTION

This manner of causation so far has not been proved capable of directly producing edema, erythema, urticaria, ulceration, hematemesis, hyperhidrosis, dilatation or inequality of the pupils, tachycardia, muscular atrophy, or any such vasomotor and trophic disturbances which were formerly included in hysteria, and it is now clear that such cases are due to physical causes[16] which are becoming less and less obscure as pathologic data accumulate *Many of these symptoms are angioneuroses*[17] which have nothing to do with either suggestibility or other psychic processes, even emotionalism

Similarly, the best observers believe that hyperthermia cannot be produced by psychic means at all, although it is now quite clear that a rise of temperature often ensues after the psychic excitation of patients suffering from hyperthyroidism[18] This, however, is due to the suddenly increased secretion of the thyroid gland, which may sometimes even cause death But if the patient lives, the temperature soon subsides and its rise cannot be considered psychogenetic in the full sense

Similarly the arrest of digestive secretion induced by bad news occurs in consequence of the emotion aroused and is strictly temporary[19] unless the emotional state is constantly reinforced from without or within When the modification endures, we have perhaps the only example of a permanent physical modification of a function not under the control of the will of which the source is directly psychogenetic Although its genesis is emotional yet as the emotion may be determined through an idea, and the idea may be implanted by suggestion, it may sometimes be legitimate to attribute to hysteria[20] this form of mental anorexia, in spite of its manifestation through a portion of the nervous system which is mainly autonomic That the autonomy of the gastric secretion is not complete, however, has been clearly shown by the researches of Pawlow[21] and Cannon,[22] and as no such dependence has been shown concerning permanent changes in the skin and mucous membranes, a better type of evidence than heretofore must be brought forward to convince us of the psychogenesis of the cutaneous manifestations at one time described with hysteria

Simulation and Hysteria—I do not wish to do more than remind the reader of the large number of cutaneous eruptions, edemas, fevers, etc, which have been produced by simulators, hysterical and non-hysterical The desire to deceive for the sport it brings or from no apparent motive is a symptom which may have nothing to do with hysteria Dupré[23] has created the term "mythomania" to characterize this group of abnormality, and every medicolegal expert and many a schoolmaster knows it well

The number of those cases which "could not possibly have had access to any means of provoking their symptoms" only indicates the looseness with which such negative evidence is accepted, as for instance in a case of alternating mydriasis which I observed in Babinski's clinic, for though the patient's father indignantly repudiated the mere statement of the fact, it was found that his daughter had been placing in her eye drops of an atropin solution filched from her employer In another case, a man confessed to concealing a syringe in the rectum, and in a moment of excitement an evacuation revealed two

Of course, mythomania, a type of moral degeneracy or of lack of adaptation by which resort is made to trickery may be accompanied by suggestibility as it generally is so that academically speaking, a deliberately produced lesion simulating spontaneous disease which the patient is trying to imitate may deserve the term hysteria, for imitation is one of the forms of suggestion Intermediate in type are the imitations of disease seen so frequently in the more ignorant hospital attendants and patients These, too, often figure as hysterics, and indeed this symptom may be induced by suggestion as in the case of nurses and patients who inflict on themselves eruptions, ulcers and swellings, or complain of palsies, contractures, vomiting of blood, etc, by the imitation of those they have seen in the hospital The mental debility which allows them so puerile an outlet for their activities permits them also to receive suggestions without criticism — that is, to be hyper-suggestible

The Stigmata are Artefacts—Unless their methods of examination act by removing the symptoms before they can be found, so to speak, the experience of Bernheim[24] and Babinski[6] clearly shows that both anesthesia and contracted visual fields and other stigmata, as Charcot called them, originate, in the vast majority of cases in unconscious suggestions of the medical examination For over twelve years neither observer has found a contracted field in a patient not previously examined Either explanation is consistent only with extreme suggestibility

THE GENESIS OF HYSTERICAL SYMPTOMS

The cause of this has not been inquired into very profoundly by either Babinski or Bernheim but attempts to account for it have been made by others The explanation which commands the most notice is that of Freud,* who ascribes it to a mental conflict which has arisen as a result of painful experiences in early childhood It is unfortunate that so many of his followers have attributed the significance of this explanation to sexual insults in themselves, for Freud distinctly says

> I passed a good way beyond my former point of view Correct the imperfections, displacements and misconceptions My former meager material gave a great many cases in which sexual seduction played the main role I overestimated the frequency of these I have since learned to explain many as an attempted defense against the reminiscence of masturbation

Freud has also disclaimed his conception that passive behavior predisposes to hysteria in these erotic events,

while active behavior results in compulsion neurosis He still believes, however, that the element of constitution and heredity really means "sexual constitution"

Although Freud still attributes the psychosis of obsessions and phobias and also the anxiety neurosis to direct perturbations of the sexual functions, he no longer imputes to this immediate cause what he calls hysteric symptoms, which he agrees are purely psychogenic He attempts to explain the state of these patients by the subconscious[25] effects of a forgotten circumstance which the patient has been unable to amalgamate with the rest of his mental life, and which he has succeeded in forgetting on account of its painful nature[26] Its memory can be recalled, however, by his "free association" method, which consists in placing the patient in a tranquil attitude and inducing him to think aloud about the events most nearly connected with his illness, and urging him to push his introspection further back[27]

Other means of recalling lost memories are the association test of Jung,[28] and the psychogalvanic reaction of Veraguth with which Jung,[20] Petersen[30] and Sidis[31] have largely worked The last has proved it to be an electromotive muscular change during emotion, occurring only during contraction

Still better known is the method of hypnosis The hypnoidization procedure of Sidis[32] seems to me closely similar to that of Freud

All of these methods have the common property of abstraction from extraneous stimuli, with concentration on the trend of thought required by the physician, in this respect the method of simple anamnestic interrogation is in many cases just as informative when conducted with skill and tact But it fails in respect to the vividness of the recollections which it recalls The patient here talks about his experiences In hypnosis and other distraction methods, the patient reenacts his experiences as he would do in his dreams[33]

In the treatment of grand hysteria, Sollier[5] has laid great stress since 1892 on the need of the patients in hypnosis to carry themselves further and further back among their infantile experiences While Freud says, "There is surely something more, think," Sollier urges, "Allez plus loin, plus en arrière." To judge by his early case reports (for he no longer considers it worth while to publish them), the results of his treatment do not show any inferiority which would lend countenance to the assertion of Freud's followers that their method of psychanalysis is a sine qua non in obstinate cases, for these recalcitrant cases are just those which find their way to Sollier

Now, from these facts it should be apparent that a hysteric symptom is one induced by an idea derived from suggestion, and that empiric methods are worse than futile, for they merely reinforce the patient's belief in bodily sickness

THE REMOVAL OF SYMPTOMS AND THE TREATMENT OF HYSTERIZABILITY

The search of the pathogen and the discovery and explanation of the causative idea of the patient suffices sometimes to remove the symptom it has caused, but it does not cure the disease To do this a course of reeducation[34] of the patient's hysterizability is needed This is not always possible in practice on account w the time and expense required, but we are now ııed position to dispense with some of the elements of tso expense I refer to prolonged isolation, overfeeding, massage, electrical applications and special nursing to which so many hystericals have been subjected on account of the secondary "neurasthenic" symptoms they have developed

I have indicated at length[35] the means of distinguishing this false neurasthenic state from the really primitive asthenia, Bernheim,[36] too, has devoted a recent monograph in part to this distinction, which is, in short, that neurasthenia, a rare condition, is a physical exhaustion either congenital, toxic or other, and that any psychic symptoms a neurasthenic may present are usually secondary and disappear spontaneously as his bodily condition improves, unless, indeed, they are maintained through the reinforcement of their suggestion by the injudicious solicitude of physician or friend[37]

---

[25] The term subconsciousness has been much abused but its consideration here would lead us too far suffice it to say that the submerged memories which determine so much of our conduct and belief can scarcely be said to act in themselves but rather by the inferences which are drawn from them and of which the subject is more or less aware, although he will not always admit their influence His denial, however is largely like that of a woman denying that she seeks a husband or of a politician denying that he is looking for an office If not merely conventional the disclaimer is dictated by a feeling of shame or by a dislike for the confession which is so good for the soul A frequent declaration of my patients is somewhat as follows I do not know why I am talking like this to you I would not dare thus reveal myself to anyone else not another person knows these things that I am telling you I hardly know them myself, etc Now this confession has not been obtained through hypnosis or other special means In one sense the patient does not explicitly feel her revelations until they are completed But could the fact that her ideas require for clear formation their focusing into a definite statement justify us in calling them subconscious? I think not for the process does not differ from the clarification of thought engendered by writing speaking or other attempts at precision of ideas which before that may have been only in adumbration Such was the means by which a patient of Flournoy (Automatisme téléologique contre la suicide Arch de psychol, 1908 reviewed by me Jour Abnor Psychol, 1909) whom some clinicians would have called a hysteric, made clear to herself for her salvation from suicide the thoughts which lingered in the back of her mind but which had been temporarily overshadowed by her despair in having to repulse her child for fear of infecting it. In a dream state she had a vision of a dear friend leading her away from the water into which she was about to throw herself. Now although the conversation she imagined was purely hallucinatory it was none the less valid as a representation to herself of ideas which took this method of formulation The mechanism is commonly used by automatic writers crystal gazers etc. who have recourse to a consultation with an oracle which they sometimes believe to be extraneous in source Others however are equally mystical in the way in which they conceive it to be another self subliminal or subconscious

[26] But is it really necessary to invoke a specific trauma to explain hypersuggestibility? Is it not a common experience that when the mind is strongly preoccupied by any course of thought, absent minded acts are the rule? What are these but immediate reactions to stimuli while the reflective processes are occupied by the dominant train of thought? In a sense that which preoccupies the patient is dissociated from the stimulus to which he reacts while absent minded and indeed from the events of daily life as long as the preoccupied state persists To this extent hysteria is a phenomenon of psychologic dissociation This explanation of its mechanism is not especially different from what Freud has called conversion Psychologically the process is the same as that occurring in suggestion

[27] It has been alleged that Freud and his followers inevitably guide the revelations of their patients toward the ideas of which they are in search and that they strongly influence the content of *the patient s thought This is tantamount to saying that some at* least of the patient s ideas arise from the suggestion of the examining physician When one remembers the ease with which even physical symptoms are suggested this objection has *a priori* much force in so delicate a field as psychologic investigation The controversy can be settled only by impartial and well trained observers working with Freud s method At all events it is becoming more and more clear that sexual traumas of early childhood need not produce a psychoneurosis and that at least the active cause of psychoneurosis in some patients appears quite unrelated to the sexual life One is tempted to believe that the enthusiasm of discovery has tended to an exaggeration of the weight of this etiologic factor especially in an age in which a reprehensible prudery has prevented its due consideration by the profession at large But it is significant that French observers of whom this fault cannot be alleged do not attach preponderant importance to the sexual factor in neurotic disturbances

[28] Jung Ueber der Psychologie die Dementia Precox Leipsic, 1906

[32] Sidis Boston Med Jour, 1907

[33] The free association of thought at which Freud aims during psychanalysis is believed by him to resemble that of the dream state But neither during the dreams of sleep nor still less in daydreams is there that complete suspension of autocritical judgment one might suppose were only the fantastic nature of dreams considered Even the bizarre images of the dream are symbols of a latent psychic content often unsuspected by the patient In the same way he interprets *a hysteric symptom as an unconscious con*version by the patient into a physical symptom of a thought which in its naked form he could not bear and it is in finding of these that psychanalysis is so useful The suppressed experiences are particularly active in dreams Hence analysis of these is most useful as a short cut to an understanding of much of which the patient s waking mind is ignorant.

[36] Bernheim Neurasthénie et psychonévroses, Paris 1908

On the other hand, the neurasthenic symptoms which are induced by a fixed idea of illness soon disappear when the patient's ideas are rectified as illustrated by my case of traumatic neurosis, and by many a woman who has arisen from a sick-bed, when exigencies or her own temper have demanded, into the full activity of normal life

ISOLATION UNNECESSARY A "UNICIST" PSYCHOTHERAPY MONISM

The fetish into which the Weir Mitchell treatment has been erected has been demolished by the recent work of Levy,[38] who shows that Dubois' way of conceiving the relation of body and mind[39] does not differ from the dualism he imagines he has transcended, and Levy points out how grossly and naively Dubois exaggerates the influence of the psyche over bodily conditions In this respect Bernheim has long transcended his former views regarding the power of hypnotism He has done so by acquiring a clear notion of the difference between psychogenic and somatogenic nervous symptoms

Now, Levy shows that true isolation is not a physical removal from environment, but a moral subtraction from fears, preoccupations, obsessions, morbid ideas, and this can be done even better in the usual surroundings than during isolation Even that bugbear of the physician, the patient's friends, can be converted into an aid instead of a hindrance, where intelligent people are concerned The chief appeal for the method of isolation is the power it gives the physician to "persuade" and reason with his patient But even this Levy believes of little use unless an opportunity is given the patient to practice the resolutions he forms, and as he cannot do this while isolated in bed, such treatment is injurious, for his best intentions will wither like a hot-house plant in the open when he has to face the stresses of his life One might as well learn to swim on a couch

Another fault of the "Weir Mitchell treatment of psychoneuroses, as often applied, is its stress on details the really important thing is that the patient thoroughly grasps the principles on which his disorder depends, and that he practice himself under the physician's direction in learning to avoid the pitfalls which life affords He must learn his own psychology, and the dependence of his bodily health on his mental state, but he must also learn that body and mind are only two sides of one thing, that bodily conditions react on his mental state, and that susceptibility to suggestions may be vastly increased by fatigue, dietetic errors or any cause of toxicosis of the neurons Even prolonged mental stimulation by the excessive interest which does not know when to stop may be a source of a neuronal state favoring suggestibility

The method of solicitude and sympathy merely reinforces the patient's belief in the validity of the idea for which sympathy is an implicit acquiescence Still more injurious is direct medical treatment of the apparent physical disorder which results from ideas For instance, a hysteric monoplegia (a paralysis of one limb induced by the patient's belief that it is disabled) should not be treated by the application of electricity or massage to that limb, or by the giving of an internal remedy which the patient is led to suppose is capable of removing such conditions It is bad practice,[37] too, to pretend to perform an operation on the patient who believes, for instance, that she is inhabited by a lizard she has swallowed Sometimes, it is true, a symptom disappears through the suggestion involved in such procedures, but it does so in a small proportion of cases only, is a pure chance, and does not touch the cause, while by ascertaining and removing the root we can generally cure permanently the present symptoms at least[40]

An illustration of the method is afforded by one of my cases of traumatic neurosis,[41] for this condition is merely the expression of an induced fixed idea of disability, which is recovered from as soon as the pathogenic idea is disposed of

Case 3—After bruising his back by a fall from a car, a railway brakeman remained for six months very lame, and the sensibility of the lower limbs appeared to be lost His tint had become sallow, and he was dyspeptic and emaciated, he was sleepless, sad and cried much The neurologic examination (reported with the case[42]) showed that there was no destruction of the nerve elements The disability was shown by psychanalysis to be a function of the false fixed idea, induced by the belief derived from his environment that such symptoms as he showed could and should follow such injuries as he had had One sitting sufficed to begin the correction of this false notion, and he himself completed the persuasion and was able to return to work in a month, as I had predicted

Beautiful examples of rational as opposed to empiric methods of treating hysteria are the following

Case 4—A woman, aged 28, whom I saw in February, 1911, with Dr Hardin, to whom she was referred by Dr Maphis of Warrenton, Va, in the preceding June had had a chill after which she cried The next day she felt very weak, and the next day she had *pain in* the knees, she thinks *only in* the left with hyperesthesia There was also, she says, tenderness of the lumbar spine, and later on in the groin and hip She was treated by massage, and for four months was relieved About Christmas time these pains recurred when her sister visited her There were then nausea and persistent dull pain in the knees which caused her to groan in her sleep

Examination was negative, except that there was great hyperesthesia of both knees and one arm Also the right abdominal reflex was absent, and the adductor reflex was exaggerated on the same side I decided that the case was psychogenic, and that afternoon attempted psychanalysis to seek the origin of the psychalgia I found two suggestive incidents one being the visit of a sister on the second occasion the other being the fact that when first attacked her brother had a severe hysteric spell He had consumption, which she feared Another fact perhaps significant was that she had been two weeks in a newspaper office during its change of ownership, alone with the man in charge much of the time

As she could stay in Washington only a short time I concluded that it would be better to remove the effects of whatever had been the source of the hysteric symptoms by psychomotor discipline than to try to pursue psychanalysis which might be unfruitful in the short time at her disposal

Method—As the least approach toward the patient's knee would set up a spasm of terror during which adductors, hamstrings and extensors went into spasm I began a course of gradual habituation first to the approach of a person's hand toward the knee, later to manipulation of the patellar region followed by pressure on it. A sister attended her in hospital and helped her to accomplish these exercises several times each day. In this way she taught herself in a few days to control the muscles around the knee joints so as to prevent them contracting when her knee was touched. The pain ceased when the spasm did, as it was in part maintained by the latter. Then her alarm vanished, as there was no reason for it, and she was satisfied that her pain lay in her own power to control. The dangers of prepossession by a fear, in conjunction with the mental vacuity engendered by lack of occupation, were explained to show the genesis of false fixed ideas regarding disease, and she was told how to avoid them.

She returned to Virginia in a week well, and has remained so for nearly two years.

Case 5.—A further case illustrating the effect of proper discipline is that of a barking, roaring and bowing tic removed in one day. The patient was referred to me by Dr. Thomas Charles Martin. He had been treated for rectal ulcer for some months. He had recently removed to North Carolina, but wanted to come back to Washington. It is possible that this had something to do with the development of his condition. I was asked to see him, because when he sat down he would utter a series of barks, while at the same time the trunk would go into a spasmodic flexion. When he was stripped, there were seen strong abdominal muscles and regular bowing of the whole body along with this barking, grunting noise.

Psychanalysis showed that these attacks had begun suddenly in North Carolina at 10 p. m. three months before. The significant fact was that he had eaten sandwiches which had been sent to him by his parents in Washington and that he had been thinking despondently before he went to sleep about how nice it would be to be in Washington. He was also thinking considerably about his intestines having been under treatment by lavage. The exact psychologic mechanism was not discovered, however.

Method.—I thought it better to remove the effects rather than necessarily to discover the details of the genesis of his tic. So I instituted a course of psychomotor discipline. The tic, which at first had come only when he lay down at night, had later occurred whenever he sat down also, and thus made life a burden. So we began by exercising in the sitting position. I placed him in a large chair, reclining, showing him how deliberately to contract the recti abdominis, and made him perform a series of respiratory movements, as well as the series of recti movements. After a few moments he became capable of contracting either the recti or the diaphragm. That being accomplishment enough for one sitting, he was asked to come back the following day. He went home and tried the exercise while recumbent at night. The result was that he came back next morning and said: "Doctor, I am cured. I did not have any spell last night." Two days later, however, he relapsed. But after another discipline, he remained well.

Thus it is simple to remove the effects in this rational way. It is so much better than the rough suggestion often attempted. For example, the last patient had been treated by electricity, which he was assured would remove his spasms. When this failed he was treated by direct suggestion. When this failed he was treated by "the most marvelous remedy known," a drug obtained from some remote country, which was guaranteed to cure. Thus, the most powerful suggestions failed in a case which was in origin suggested and conformed to Babinski's definition of hysteria, "susceptible of production by suggestion." A motor habit had been formed, and the removal of all habits requires reeducation of the patient's volition. Indeed it is only by its action on the will that suggestion ever succeeds.

Now, although hysteric symptoms are always psychogenetic and have a mechanism the knowledge of which enables the clinician to penetrate to their origin, yet hysterizability varies with bodily states,[43] so that the treatment of hysteria cannot safely be left to those laymen who have arrogated to themselves the title of psychotherapeutists by an assumption which is justifiable only to the minds of dualists and those who attach no validity to the old adage which becomes more and more true as our psychologic knowledge broadens and deepens, *mens sana in corpore sano*.

The application of the principles described in this article is shown in ten cases which I recently reported.[44]

1705 N Street, N. W.

THE DIAGNOSIS OF TUBERCULOSIS OF THE KIDNEY IN VERY EARLY AND VERY ADVANCED CASES

PROGNOSIS AND TREATMENT *

THORKILD ROVSING, M.D.
Professor of Clinical Surgery at the University of Copenhagen
COPENHAGEN, DENMARK

It is generally assumed, and I myself once cherished the conviction, that with every surgical tuberculosis of the kidney — even in the earliest stage — albuminuria must occur, and that one would therefore be justified in excluding the diagnosis of tuberculosis of the kidney when the examination of the urine for albumin gives a negative result. But of late years a series of observations has shown me that this is not the case, as we see some cases in which the albuminuria is intermittent, and others in which it seems to be invariably absent.

Among my cases, about 200 in number, I have established the diagnosis seven times in such circumstances.

In reality, cases of this sort are undoubtedly far more frequent, because just the belief of the necessity of albuminuria with tuberculosis of the kidney has surely resulted in most physicians not having thought of or searched for tuberculosis in such cases.

Case 1 is that of a man who, on account of albuminuria, was treated in a medical ward during nine months for chronic nephritis. The albuminuria having ceased, it was thought that the man was cured of the nephritis and he was consequently discharged. A day or two afterward he was admitted to my clinic, without question free from albuminuria, but, as was clearly substantiated, with an enormous tumor on the right side of the abdomen, which proved, at the ensuing operation, to be the right kidney which was completely destroyed by infiltrating tuberculosis, so that literally no kidney tissue was found, this being replaced everywhere by a cheese-like mass. No pus was found, the mucous membrane of the ureter was certainly very inspissated, but there was no sign of obliteration. This is, then, an interesting example of how the urine can, in extremely advanced cases, be free from albumin without closure of the ureter, apparently because all secreting kidney tissue is destroyed. But in most cases the absence of albuminuria has occurred where the tuberculosis of the kidney is of relatively recent date or is strictly limited. It is clear that such patients arrive in the surgeon's hands only when they present other conspicuous symptoms.

* Read in the Symposium on Renal Surgery and Pathology in the Section on Genito-Urinary Diseases of the American Medical Association at the Sixty-Third Annual Session, held at Atlantic City, June, 1912.

* Because of lack of space this article is abbreviated in The Journal. The complete article appears in the Transactions of the Section.

In a group consisting of three cases (Cases 3, 4 and 5) it was hematuria, with or without pains, which brought them to me The first case (Case 3) was very interesting partly because the symptoms had existed during five years, and partly because, even with the removed kidney under our eyes, the diagnosis was doubtful The patient was a woman of 30 years, who, five years previously, had suddenly begun to suffer from left-sided pains in the loins and from hematuria The hematuria lasted only for four days, but the pains continued during the following eleven months, the result being that she was daily treated with morphin at the infirmary where she lay During the following three years she was free from pain, but then the attacks of pain and hematuria recommenced No trace of albumin was found in the urine, and leukocytes were found only occasionally, while we did not succeed in proving the presence of tubercle bacilli At the operation on June 3, 1908, I found a whitish-yellow tumor, the size of a nut, protruding from the middle third of the kidney When the kidney was split, it was seen that the tumor mentioned consisted of pork-like whitish tissue which did not resemble the recognized aspects of tuberculosis, and, furthermore, the upper and lower kidney papillæ were found to be infiltrated with similar tumor tissues The diagnosis vacillated between carcinoma and gumma, but the microscope revealed typical tuberculosis

That this tuberculosis which so peculiarly resembled tumor did not involve albuminuria can be explained without any great difficulty. It is more difficult, however, to understand why Cases 4 and 5 showed themselves during a long-lasting examination to be free from albumin, because, in both cases, abscesses and miliary tubercles were found in the kidney at the operation In Case 4, that of a little girl 9 years old, the hematuria was severe but painless, and the only symptom left which could be relied on was the discovery of leukocytes in the urine, on the other hand, neither tubercle bacilli nor albumin were found In Case 5, however, the hematuria was associated with pains in the discharge of the urine, and, as a considerable tuberculosis of the prostate and ulcerations in the bladder were found — though no albumin — it was most natural to think that an ascending genital tuberculosis was in question, but it was not until, on catheterization of the ureter, leukocytes and tubercle bacilli were found in the albumin-free urine from the left kidney that suspicion was centered on this

In Cases 2 and 7 it was only the attacks of pain occurring in the region of the left kidney which brought the patients to me All that I had whereon to found my suspicion of tuberculosis in Case 2 was the pus-celled contents of the urine, without my being able simultaneously to prove the presence of microbes of any sort In Case 7 the diagnosis was rendered still more difficult by finding in the urine of the bladder, in addition to the pus-cells, some Gram-positive coccobacilli It was only on catheterization of the ureter, when it appeared that the urine from the left kidney contained pus-cells without microbes, that a suspicion of tuberculosis was aroused, and then, by persistent investigations, I succeeded in finding tubercle bacilli Finally, Patient 6 was one on whom I had several years before performed a right-sided castration for tuberculosis in the testis and epididymis, and who was now admitted with tuberculous left-sided epididymitis There was no albumin in the urine when he was admitted, but as, later on, a little was occasionally found, I made a cystoscopy, and found a small ulceration in the bladder medially before the orifice of the right ureter, and as, on catheterization of the ureter, leukocytes were found in the urine of the right kidney, an exploratory lumbar incision was made At the operation I was surprised to find the entire kidney degenerated by small cysts, without there being any macroscopic sign of tuberculosis, while on the other hand, a stricture was found in the ureter

After the removed kidney had been cut through, only the aspect of a cystic kidney was to be observed macroscopically, but, scattered in this, the microscope revealed small tuberculous foci

Then there are the cases in which the urine contains visible pus and in which the diagnosis is pyelitis, and the patient is treated with salol, boracic acid or similar remedies But even the symptoms of cystitis do not by any means always bring the physician onto the right track, the only result is that he often, without a more thorough examination as to what form of cystitis he has here to deal with, blindly attacks, so to speak, the disease with the ordinary cystitis remedies, such as nitrate of silver injection, which is exceedingly painful, entirely useless, and often apparently aggravates the cystitis These patients are in a still worse plight if, for a short time previously, they have been suffering from gonorrheal urethritis, because the cystitis is then taken to be gonorrheal and treated with protargol or, what is still much worse, with the Janet daily lavage, a solution of permanganate of potash, which appears to have a particularly injurious effect on the mucous membrane of a tuberculous bladder, this treatment, at all events, appears to have had a fatal influence in two of my cases

All these regrettable errors in diagnosis might be avoided if only physicians fully realized that one ought never to begin the treatment of albuminuria, pyuria or cystitis without first having subjected the urine, sterilely taken from the bladder, not only to a chemical but also to a microscopic and bacteriologic examination

I am quite aware that it is maintained to be very difficult to prove the presence of tubercle bacilli, even in the newest handbooks, such as Kuster's and Wagner's, it is stated that attempts to show the presence of tubercle bacilli in diseases of the urinary tracts are successful in only 10 to 20 per cent of the cases With reference to these statements, I can only say that the authors must have adopted unfortunate methods or have not persevered long enough, for when I look over the statistics from all my cases it appears that the assured presence of tubercle bacilli has been successfully shown in 80 7 per cent of these cases The method which I have used with such good results is that of Forsell, according to which one lets the aggregate urine of the twenty-four hours precipitate in a separator The lowest portion of the precipitate which contains the tubercle bacilli is separated, and can then in addition be centrifugally treated before being put under the microscope

For a practitioner all such circumstantial methods, as a rule, are entirely unnecessary, for simple microscopy with ordinary microbe coloring is sufficient to give him the diagnosis, if he finds pus in the urine but no microbes, the diagnosis of tuberculosis is almost certain the case is at least so suspicious that the patient must at once be sent to a place where a special examination by experts can be undertaken, for in all other suppurative kidney affections we find numerous easily colored microbes in the urine

The use of ureter catheterization, more especially in tuberculosis of th [illegible] many enemies [illegible] no doubt princ [illegible] ization is so [illegible] time, but a [illegible] sibly sound ureter, and even if we maintain that this risk, as far as experience shows us, is very slight, yet its existence cannot be denied, and it would be desirable if we could manage with cystoscopy alone, or with segregators According to my experience, this, however, is entirely impossible Cystoscopy pure and simple is always uncertain, in some cases we can, of course, see undoubtedly purulent urine flow from the orifice of the ureter and thus be tolerably certain of the kidney in question being affected, but we are then left entirely in the dark as to the state of the other kidney, for a macroscopically clear urine is not by any means synonymous with a normal urine What cystoscopy, generally speaking, should enlighten us about are alterations in the shape of the orifice of the ureter, swellings, miliary tubercles and ulcerations around the diseased orifice of the ureter But you will find that the tuberculous alterations in the bladder in only a minority of the cases are localized around the diseased ureter In some cases you will see that the bladder tuberculosis, in a directly misleading manner, has localized exclusively round the orifice of the sound ureter You will find cases in which both kidneys are affected, but both ureteric orifices are free from alterations, or in which the tuberculosis has localized round the orifice of the one ureter, but in by far the greatest number of cases you will see that bladder tuberculosis in one-sided kidney affection is spread over both sides or halves of the bladder, sometimes over the whole of the mucous membrane of the bladder

Therefore, this method ought not to be allowed to take the place of, or be put on a level with, ureter-catheterization, which is the only bloodless method which can give us certain knowledge of the state of the kidneys It is necessary to warn against the use of segregators, which are so tempting because of the technical simplicity of the method which any one can apply, while ureter-catheterization requires special training and practice

The examination of the urine taken from each kidney must be undertaken with great care and judgment, it must be subjected to a thorough chemical, microscopic and bacteriologic examination

At the Congress of Surgeons held in Berlin in April, 1905, I, for the first time, drew attention to the importance of diagnosticating toxic albuminuria, and in my introductory address to the discussion on nephrectomy in kidney tuberculosis, I mentioned five such cases in which, in spite of a fairly pronounced albuminuria from the other kidney, I had extirpated the tuberculous kidney, and had afterward seen the albuminuria disappear in the course of a very short time, the patients being cured To these, from subsequent personal experience, I can add eight new cases

The double lumbar incision has been used by me in thirty of 166 cases, and I have never lost a single patient by this method In twenty-four cases I ascertained the one-sidedness of the disease, which could not have been ascertained by any other means I removed the diseased kidney, and in all cases recovery was the result, in one case I found the kidneys healthy, in six cases I ascertained the double-sidedness of the disease, in four of these I closed again without proceeding further, in two cases I undertook ureterostomy to procure relief from pains and to arrest the process of ascending tuberculosis

One of these cases is of considerable interest A girl, 26 years of age, was brought to my ward in a very wretched state The bladder was found to be completely infected by typical tuberculosis, the mucous membrane around both the ureter orifices was ulcerated and the insertion of the catheter was impossible into either ureter on account of stricture By palpation the right kidney was distinctly found to be somewhat enlarged, the left kidney could not be felt, but by means of Roentgen rays a big oblong shadow was discovered corresponding to the left kidney The picture could not decide the question as to whether this was a large calculus or, what I was most inclined to assume, a calcified tuberculous kidney I decided on exploratory lumbar incision on the right side, whereby I made the following interesting discovery The appearance of the kidney itself was normal, but the pelvis had expanded to the size of a Tangerine orange, the ureter was distended to the thickness of a finger, the upper serpentine portion of which was thin and transparent, while the ureteric wall from about the middle was found to be at an increasing rate thickened by interstitial ureteritis I then, in the first instance, brought the ureter forward and formed a ureterostomy by a longitudinal incision on the outer side of the ureter I carried a drain up into the pelvis and through it drew off a perfectly clear urine, which was free from albumin, and which microscopically contained only a few leukocytes By sounding the distal portion of the ureter I found an exceedingly narrow stricture, which commenced a few centimeters above its opening into the bladder The urine was carried through a drain, which had been inserted into the pelvis, down into a glass by the side of the bed, and during the following days it transpired that the other kidney did not yield any urine at all but only some tuberculous pus In the course of a few weeks I removed the left kidney, which had been completely transformed into a tuberculous putty-like substance The ureter fistula was kept open until the bladder tuberculosis was cured by phenol (carbolic acid) treatment, of which I shall speak later on The passage through the ureter was then reestablished, and the kidney has now for six years officiated satisfactorily

In two cases I punctured an abscess in the kidney as large as a hen's egg

I have, ever since 1892, systematically undertaken quantitative analyses of urea with all my kidney patients prior to operation, and found that a normal secretion of urea is a safe criterion of a sufficiency of kidney tissue capable of functionating, but that, on the other hand, nothing can be gathered from a reduced secretion, inasmuch as the latter directly or indirectly can be due to the diseased kidney — directly by a purely reflex effect on the secretion of the sound kidney (renorenal reflex), indirectly by the disease actuating the functions of the whole organism I have shown this in a whole series of cases in which the secretion of urea, after the removal of the tuberculous kidney, from being diminished, quickly rose to normal height While a normal secretion of urea imparts a very important and satisfactory knowledge, it is, on the other hand, very risky to adduce from a slighter secretion of urea that both kidneys are inadequate, this may serve as a warning to proceed cautiously, but nothing beyond that

With regard to all the rest of modern kidney-function examinations, I have shown that these are still more unreliable than the urea analysis, for while the latter misleads only by a negative result, both chromocystoscopy (Achard's methylene-blue test, Voelker's indigo carmin), cryoscopy and the phlorizin method are capable of misleading by positive as well as negative, results I have, therefore, entirely given up these artificial and complicated methods in favor of the simple and rational quantitative urea analysis, which I make by the aid of Esbach's ureometer

In recent years, the conception of the prognosis has become so optimistic that several authors maintain that early cases of kidney tuberculosis ought to be treated conservatively — by dietetic measures and with tuberculin, while nephrectomy should be allowed only in very advanced unilateral cases

In my opinion this doctrine is wrong and very dangerous First, because we never know whether the case is early or advanced, malign or benign Behind the slightest, most veiled symptoms the most advanced, the most malignant tuberculosis may be hid, as recently proved by some of my cases Second, there exists no convincing case of tuberculous kidney cured by conservative treatment As now the statistics have established that we, by nephrectomy, can save 75 per cent of all patients operated on, it seems quite clear that nephrectomy is indicated as soon as we have diagnosed a unilateral kidney tuberculosis In spending the time on conservative treatment you run the risk of spreading the tuberculosis to the bladder and to the other kidney, and thereby destroy the possibility of a radical cure

If we should define the position of the question at the present moment, I consider that, generally speaking, I can maintain that the possibility of a radical cure is dependent on two conditions (1) that the point where the tuberculosis originates within the urogenital organs can be radically removed and (2) that at least the one kidney is sound

As far as the descending tuberculosis of the urinary tract is concerned these two conditions of course go together if only the one kidney is attacked there are chances for a cure by nephrectomy With ascending urogenital tuberculosis both conditions have to be reckoned with, inasmuch as the tuberculosis here originates in the genital organs but often secondarily spreads to the kidneys This double and complicated state of affairs must at the outset make it probable that the prospects of a cure would be considerably slighter with ascending urogenital tuberculosis The prognosis for ascending urogenital tuberculosis is much more serious than for descending, and this is partly due to the fact that while primary kidney tuberculosis in the great majority of cases is one-sided, secondary kidney tuberculosis is just about as often double-sided as one-sided, and partly to the hopeless course which a breaking through of the tuberculosis from the prostate to the bladder and urethra most frequently takes, attended by extravasation of urine, fistula formations, etc

If, on the other hand, only the epididymis, vas deferens and a single kidney are attacked, there is every prospect of cure through the removal of the epididymis and the diseased kidney, even if the bladder should be also attacked This latter complication, up to a few years ago, was considered so serious that it was looked on as an absolute contra-indication to operation We know now, through numerous instances, that a slight bladder tuberculosis is frequently cured spontaneously when the place where the tuberculosis originated is removed but even with extensive bladder tuberculosis, which excludes a spontaneous cure, there is every chance of bringing about a cure by means of treatment with a 6 per cent phenol solution with which up to the present time I have cured thirty-four patients

In all the cases in which, by means of the diagnostic aids I have just described, I have proved that only the one kidney was attacked, I have removed it by nephrectomy In all I have performed 145 nephrectomies for kidney tuberculosis with but seven deaths — that is, 4 8 per cent mortality There were two deaths in the first fourteen operations, which were performed in 1901 — a 14 2 per cent mortality — while there have been only five deaths out of the 131 nephrectomies performed after 1901, that is, 3 8 per cent

I use a long slanting lumbar incision, open the fat casing of the kidney at the back, loosen with great care by means of my rubber-gloved hand the kidney from its bed and possible adhesions, examine and palpate it minutely in order to verify the diagnosis, then draw the ureter forward on my bent left forefinger, tie it up in two places with strong silk thread in order to burn it slowly through with a red-hot thermocautery between the silk threads about 3 cm below the entrance into the pelvis I then isolate this from the vessels in the pedicle, which is tied up with strong formaldehyd catgut, after which the kidney is removed by cutting through the vessels The peripheral end of the ureter is fastened to the skin 1 cm from the wound-line, whereby I insure the raw surface of the abdomen against any possibility of infection from tuberculosis Formerly, when I removed as much of the ureter as possible and lowered the stump, the latter often became the starting-point for an exceedingly dangerous diffused tuberculosis in the retroperitoneal tissue and in the abdomen

In case one or both the epididymides are attacked, an extirpation of the epididymis is performed at the same or a subsequent operation, with the preservation of the testis if the latter be not attacked As to the severed vas deferens, it is treated in a similar manner as was the ureter it is sewed forward to the scrotal skin, where it, when the wound is otherwise healed, is kept open as a safety-valve for the tuberculous secretion, which might be in the peripheral parts and in the vesiculæ seminales I have adopted this method in connection with nephrectomy in a large number of cases and always with good results If there is tuberculosis of the bladder I wait some time after the nephrectomy to see whether the bladder tuberculosis will heal spontaneously, which I ascertain by performing cystoscopy every fourteen days

In fourteen cases spontaneous healing resulted simply in consequence of the source of the infection having been removed with the kidney, but in the remaining thirty-four cases there was no such spontaneous healing Sometimes, contrary to what is generally the case, quite a small tuberculosis was seen to spread incessantly, assuming a very vicious character, but in these cases the bladder tuberculosis was, as a rule, already far advanced when the patient came into the hospital It is these cases that I have subjected to local treatment with a 6 per cent phenol solution This treatment, which to begin with is undertaken every other day, consists in first washing out the bladder with sterilized water, and then injecting 50 c c of freshly made, warm, 6 per cent phenol solution, this is allowed to remain for two or three minutes and comes away as a perfectly milky fluid These injections are continued until the phenol lotion comes away fairly clear

The effect of this treatment, which, as a rule, manifests itself astonishingly quickly is shown by the cessation of the pus secretion and by the clearing of the urine By degrees, as the urine becomes clearer the injections are made at longer and longer intervals, and are discontinued when it has been shown by cystoscopy that the mucous membrane of the bladder is healed This we can see by the ulcerations in the cy[illegible]ic picture being replaced by sm[illegible]r-of-p[illegible]atricial areas With wide [illegible]alo[illegible]eeks treatment is, on an average, necessary If the patient and the physician have the perseverance to carry through the treatment, a cure is certain, subject to two conditions (1) that the source of infection is removed, and (2) that the tuberculosis is confined to the mucous membrane and has not spread through the walls of the bladder It is only subject to these conditions that the adoption of this treatment can be at all recommended The first patient treated in this way, and in whose case the tuberculosis was of an unusually vicious nature and extending over the whole of the bladder, has now been well for five years

I have of late gone still further in my attempts to save apparently hopeless patients, as, for instance, in the case I have already mentioned while speaking about the diagnosis, in which the double lumbar incision showed me that the tuberculosis had proceeded from the completely destroyed left kidney, traveled through the ureter to the bladder, the mucous membrane of which was completely ulcerated, and from there had again ascended to the right ureter and there produced stricture and distention In this case I performed extirpation of the left kidney and lumbar ureterostomy on the right side, by doing this I prevented the tuberculosis from ascending to the other kidney, which was still sound I kept the fistula open until I had cured the bladder tuberculosis by phenol treatment and dilated the ureter stricture The passage through the ureter was then reestablished, and the patient is still, six years after the operation, living and free from pains of the bladder, the right kidney officiating satisfactorily

As a palliative operation I use and strongly recommend ureterostomy in cases of double-sided ascending kidney tuberculosis in which stricture with distention of the ureter and pelvis causes great pain In such cases we not only relieve the patient completely from pain but, by establishing a free outlet, arrest the upward progress of the tuberculosis, and prolong the patient's life Neither is it probably altogether out of the question that, at an early stage, an ascending kidney tuberculosis can be cured in this manner Formerly I used a catheter or drain introduced into and fixed in the ureter, which through the bandaging was carried to a concave-convex bottle which was tied to the lumbar region by a belt, but the frequent escape of the urine by the side of the catheter and the drawbacks resulting therefrom led me to construct a bandage consisting of a small silver capsule fitted with a rubber ring, which, by means of an elastic girdle round the abdomen, is kept tight round the ureter fistula, and from which a small silver tube through a drain leads the urine into a urinal

I have already mentioned that the group of cases in which tuberculosis is primary in the prostate and from there directly attacks the urogenital organs invading the urethra and the bladder gives an exceedingly bad prognosis, on account of extravasation of urine and the formation of abscess and fistula in the connective tissues of the pelvis Yet in some cases it is possible to obtain partly curative, partly palliative, results through operative methods

Where tuberculosis of the prostate has as yet only attacked the urethra, while the bladder is sound, I perform suprapubic cystostomy with insertion of a Pezzer catheter and then extirpate the prostate, removing in connection with the latter the diseased portion of the urethra

As a palliative measure, I have seen excellent results from suprapubic cystotomy in cases in which a radical operation has no longer been possible

THE USE OF TUBERCULIN IN THE TREATMENT OF SURGICAL UROGENITAL TUBERCULOSIS *

GEORGE S WHITESIDE, MD
Genito Urinary Surgeon to Multnomah County Hospital
PORTLAND, ORE.

My paper is not a didactic or an authoritative scientific exposition of the subject from the point of view of the tuberculin therapist but rather a synopsis of personal experience and opinion from the point of view of the genito-urinary surgeon

It is sometimes stated that the modern surgeon is so filled with scientific enthusiasm that he loses sight of the human side of his work and only thinks of his patients as cases I do not believe this is true except in very exceptional instances I want to emphasize this fact because in tuberculosis, to an extent that is equaled in scarcely any other disease, the social, economic and human factors are of very great importance This is so because tuberculous patients are, as a rule, young persons who are, or should be, doing each his or her share of the active work of the world Also because of the often wide-spread destruction of tissues or organs and yet, unlike in cancer, the disease is not necessarily fatal even though total extirpation be proved impossible

There have recently come to my notice two excellent papers, one by Dr Paul Thorndike of Boston on renal tuberculosis, and one by Dr J D Barney of Boston on tubercle of the epididymis Both of these papers are entirely from the point of view of operative surgery In both the use of tuberculin is mentioned Dr Thorndike believes renal tuberculosis should never be temporized with and Dr Barney only briefly mentions any other than operative treatment In every other way I entirely agree with the sound conservative opinions expressed in these papers It seems ridiculous to believe that tuberculin therapy can heal advanced lesions with considerable breaking down of tissue, nor can it ever be expected to absorb considerable collections of pus Where there is an abscess or much necrotic material surgical intervention is essential Where a kidney is a mere sac full of pus it would be a foolish waste of time to do anything but remove it Where the epididymis or seminal vesicle or prostate is a broken-down mass of purulent necrotic material the knife is the most conservative remedy Any other course puts the patient's life in jeopardy and is expecting too much resistance to infection of the general organism On the other hand, there are frequent conditions in which either all the operative surgery has been done which it seems wise to do or in which, for other reasons, operation should be either postponed for a time or is contra-indicated altogether Perhaps I can best illustrate this by specific instances

Case 1 —R B, male, aged 20, in February, 1911, began to have frequency of micturition while at college in Berkeley, Cal The patient was examined by Dr E McConnell, of San Francisco, who found evidence of tuberculosis of the right kidney and bladder Bacilli were found in the urine In May, 1911, the patient consulted me in Portland and I began treatment with tuberculin Immediate and very marked improvement resulted Koch's Old Tuberculin, as put up by Mulford, serial dilution No 1, was the preparation used Very minute doses were administered without any attempt to reach the limit of tolerance In fact, every effort was directed to give so small a dose that there should never be any specific

---

* Read in the Symposium on Renal Surgery and Pathology in the Section on Genito Urinary Diseases of the American Medical Association at the Sixty Third Annual Session held at Atlantic City June, 1912

reaction I believe this to be of great importance In August, 1911, the patient returned to college As it was important for him not to have his course of study interrupted, this was the justification for not at once taking out the offending kidney Also we were encouraged to continue the tuberculin on account of the extremely favorable result of a few weeks' treatment in the spring and early summer of 1911 On his return to Berkeley he consulted a specialist in pulmonary tuberculosis I believe that, in the light of later developments in the case, this was a mistake The patient, however, seemed to have great faith in this specialist and for a time did fairly well Then the specialist tried the plan of giving him tuberculin in increasing doses up to the limit of tolerance Occasionally this limit was passed and the boy had fever, chills and other evidences of an overdose However this method may succeed in pulmonary cases I do not know, but I am convinced it will always make surgical patients worse I believe the safest guide, as I have repeatedly said before in discussing this subject, is the irritability of the bladder An overdose is shown by increased pain, frequency and bladder irritability far sooner than the point of the production of constitutional symptoms Of course, bladder symptoms are not invariably present in renal cases It soon became evident that the boy was getting worse. In November, 1911, he returned to Portland and I removed the right kidney Since then his general health has gradually improved Just after Christmas, 1911, he went to visit his relatives and I have not seen him since He writes that his condition is good

I report this case not as evidence of the triumph of the use of tuberculin but because I believe, though I may be mistaken, that the unwise administration of tuberculin by the method of dosage almost or quite up to the limit of tolerance actually precipitated an early nephrectomy which might have been deferred until a more convenient time or possibly avoided altogether

There is another class of cases which are very troublesome to both physician and patient In women we frequently see cases of painful and frequent micturition In those cases in which gonorrhea can be absolutely excluded and in which there is no colon bacillus infection we must seriously consider tuberculosis We must also exclude traumatism of the urethra from excessive coitus Modern investigation has led to the conviction that primary bladder tuberculosis is very rare Many of these cases are undoubtedly dependent on renal tuberculosis, although there are apparently a few exceptions

Case 2—In April, 1910, Miss S, aged 30, single school teacher, consulted me She said that for years she had had attacks of painful frequency of urination Latterly they had been of longer duration and much more troublesome Examination showed a normal urethra except for some injection and great sensitiveness at the inner meatus and this seemed continuous with a neck of the bladder irritation There was absolutely no evidence of gonorrhea in the past or present history Cystoscopy showed a normal bladder except for the injection of the vessels at the bladder neck The ureter orifices were normal. Ureter catheterization brought normal urine from both kidneys There were no subjective symptoms of kidney disease The bladder urine, on the contrary, contained a slight amount of pus and tuberculosis was suspected but the bacilli could not be demonstrated The application of nitrate of silver and dilatation of the urethra proved effective in giving relief for a time This patient's work is exacting She teaches the youngest children in a large public school Her urinary frequency increased daily from Monday to Friday The Saturday Sunday holiday gave a chance for slight betterment of symptoms She is absolutely dependent on her work She is unfitted for other employment It is therefore imperative that she continue her work As I said no evidence has been brought forward of kidney disease In January, 1911, tubercle bacilli were demonstrated in the urine Tuberculin treatment was begun and persisted in since There has been marked benefit apparently attributable to this treatment She is very susceptible to an overdose and only 0 005 c c of Old Tuberculin No 1 can be given without bladder reaction This means, in my opinion, delay The good results of tuberculin are undoubtedly more quickly apparent in a patient who can take a somewhat larger dose than this In the course of time, however, her improvement has been quite marked In what way could operative surgery have been of benefit in this case? Possibly, as Dr Thorndike says in his monograph above referred to, the condition will remain about the same for years and later a renal disease will show itself and eventually nephrectomy will have to be done Time alone will tell

Case 3—I have previously reported the case of a nurse with a very extensive generalized tuberculosis of the abdominal viscera including the bladder and intestines After two years treatment with tuberculin (Koch's Old Tuberculin) in very small doses she entirely recovered and now, four years after beginning treatment, she is well, back at her work and showing no discoverable evidence of disease

Case 4—The patient, with tuberculosis of the genital tract, was first seen in 1908 At that time he showed very advanced disease and was operated on to eradicate as much disease as possible Afterwards he was treated for a few weeks with tuberculin He reported to me in February, 1912 He was apparently perfectly well There was no evidence of any disease He felt strong and well and had gained weight

Another class of cases are those with bilateral renal disease of an advanced type or those showing pulmonary infection in addition to the urinary tuberculosis These cases are hopeless Neither operation nor tuberculin nor a combination of the two will cure If any such patient gets well it is in spite of and not because of treatment I have never seen such a patient recover Sometimes one will seem to do well for a time but eventually, in my experience, some fatal lesion develops

I do not think treatment of any case, in any stage, by tuberculin, is as satisfactory as one could wish it to be It is just about on a par with bacterin treatment of any other condition Eventually someone will discover a better method but in the meantime a great deal may be accomplished by using the various preparations of tuberculin I have tried to show that they are mainly aids to surgical or other treatment and that, even in competent hands, they may be very disappointing If tuberculins are used without good judgment as to dosage much harm can be done, in fact, often irreparable harm The exact preparation chosen I believe largely a personal matter One surgeon will get good results with O T, another with B E, and still another with some other preparation It depends on which the surgeon is most used to working with, because, at all times, in every case, it is necessary to be cautious, patient and watchful and to be guided by the results of personal experience I have tried the opsonic index as a guide but believe that it merely introduces another element of uncertainty and error without rendering compensating advantages The symptoms of the patient, carefully observed and properly interpreted, are guide enough There are almost as many ways of handling tuberculin as there are physicians who use it It would waste your time if I should tell you any of my tricks of technic because, although they suit me, your own doubtless fit you better and accomplish the same result in the end

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS ROVSING AND WHITESIDE

Dr William T Belfield, Chicago At a clinic given to the American Uro[illegible] tion in Chicago, in September 1911, I presented [illegible] wit[illegible] bercul[illegible] male treated with [illegible] h during the past six years has convinced me that in genital tuberculosis the knife has no place, except to evacuate débris Following is a report of one of the six cases I showed at that time

A man, aged 27, had had one testis removed for tuberculosis The remaining epididymis was three times as large as the testis, the urine was thick, containing pus, blood and tubercle bacilli, and he urinated every half hour day and night He had lost 18 or 20 pounds in weight The advice which he had received from excellent surgeons was to have the remaining testicle, the prostate and the seminal vesicles removed He received simply tuberculin as treatment, being unable even to secure the benefit of outdoor life When I showed him to the American Urological Association a year later the man was apparently as well as any who inspected him, the urine clear, the fistulas had healed and his weight had increased The other cases were not so advanced, but the effects of treatment were equally good These are illustrations of the experience which has convinced me that the knife has no place in the treatment of genital tuberculosis in the male, except for the removal of débris I would not, with my present experience, substitute tuberculin for the knife in the treatment of tuberculous kidney

Dr **Hugh H Young**, Baltimore Dr Rovsing's method of treating the ureter is somewhat unique I would like to ask whether he treats the ureter internally at all after the operation, whether it is necessary to treat the ureter while treating the bladder, and whether he attempts to have the fluid from that ureter come out through the wound rather than through the bladder while he is treating the bladder with the phenol (carbolic acid) solution It seems to me that after excision of a tuberculous epididymis it is extremely important to bring the vas out through the groin, to inject it with phenol or iodoform, and to leave it to drain as long as possible. We have followed Dr Rovsing's work in regard to the phenol treatment and have not obtained the results he has, I think this is because we have not persisted and done it as frequently as he has We are perhaps frightened by the pain caused the patient I do not believe I can report any remarkable results in renal tuberculosis Certainly in other forms of genito urinary tuberculosis, particularly if localized, we may sometimes get brilliant results

Dr **Guy L. Hunner**, Baltimore If we could get the profession at large to appreciate that, if there are a few leukocytes in the urine of a patient with bladder symptoms, and no culture can be grown from the urine, we can almost safely assume that that is a case of tuberculous kidney, it would go a long way toward simplifying the treatment of this disease

There are a few cases in which there is thickening of both ureters, and with care and patience, we can usually determine which of the ureters is actually tuberculous and which is suffering from interstitial thickening from absorption upward from the bladder I have had three cases in which I could not catheterize the supposedly good side because of this interstitial ureteritis I was fortunate enough however, to be able to catheterize the bad side, and by washing out the bladder thoroughly and collecting the urine I got a fairly good idea of what the supposedly good side was doing operated in spite of this thickening at the lower end of the ureter, and in each of the cases had a perfect healing of the ureteritis and a disappearance of the cystitis

Dr **Thorkild Rovsing**, Copenhagen I ought to have said in my paper that I treat the ureter very often by injecting phenol solution through the ureter In most cases it is astonishing to see how it closes up without any treatment, the walls growing together and the tuberculosis healing with building of fibrous tissue

I keep the ureter open until the bladder is cured to save the patient the pain involved in voiding urine The urine would irritate, and it is an enormous relief for the patient to be free from that until the bladder is healed Therefore, I recommend in hopeless cases in which the patient has dreadful pain from the ulcerations in the bladder a ureterostomy, because it does away with all the pain There is no more need to pass the water through the bladder, and therefore there are no more pains

DECAPSULATION OF THE KIDNEY*

D S FAIRCHILD, M.D

CLINTON, IOWA

During the past few years a great number of decapsulating operations have been performed on the kidneys for the relief of diseases of these organs The limited resources of medical treatment have called the attention of surgeons to these organs in a special way and have led to surgical procedures which have very little scientific foundation for the undertaking It therefore follows that the merits of the operation can be determined only by the study of a large number of cases and not by any process of abstract reasoning

It would not be fair to say that the work has been altogether empirical The pathologic considerations which have led to decapsulation and incision of the capsule and of the kidney itself have rested on the assumption that freeing the capsule or incising the kidney has a modifying influence on the circulation of the organ and thus brings about an improved nutritive process leading to an ultimate restoration of the kidney to the normal or to relief of the organ from a pressure to the delicate kidney structures whereby its function is resumed and recovery follows, or in less severe and in more chronic conditions the structure of the kidney is saved from damage It may easily be assumed that considerations like these have influenced surgeons in undertaking decapsulating or decompression operations

Reginald Harrison of London appears to have been the first to undertake to relieve the intracapsular pressure of the kidneys by a simple incision in albuminuria, hematuria, anuria, pains, etc , of the inflamed kidneys This was in 1878 His favorable results induced other clinicians to attempt to improve the disturbed functions of the kidneys, improving urination by nephropexy, loosening adhesions, and by ureteroplastic operations

Le Dentu in 1881 performed a splitting of the capsule of the kidneys to allow the parenchyma of the kidney more expansion

Following the deliberate clinical work of Harrison and of Le Dentu, other workers undertook to show experimentally what changes actually occurred so far as the kidneys themselves were concerned N H Gifford,[1] in experimental work on decapsulation of normal rabbits and dogs, of dogs with induced nephritis and of dogs with infarcted kidneys but with additional work thrown on them, found the following conditions In all of his cases the entire thickness of capsule over two-thirds of surface, a certain amount of intracapsular tension in undecapsulated kidneys — normal or nephritic — shown by immediate increase in decapsulated kidneys up to one month after, a decrease to normal complete at six months, congestion of intertubular vessels of cortex, casts three to five days after the operation, no change in renal epithelium after decapsulation, a new capsule very vascular at first two to four times the thickness of the old marked at end of eight days In six months return to normal new capsule, in part from retroperitoneal connective tissue, also intertubular connective tissue, no new blood-vessels anastomosing with those of the kidney

---

* Because of lack of space this article is somewhat abbreviated in The Journal. It appears in full in the Transactions of the Section and in the author s reprints

[1] Gifford N H Experimental Decapsulation of the Kidneys Div Surg., Med School Harvard Univ Boston 1903-04 Experimental Decapsulation of the Kidneys, Boston Med and Surg Jour , 1904 cli, 37

G Herxheimer and W Hall[2] from animal experiments reach the following conclusions

1 After decapsulation the capsule forms anew and becomes thicker than normal
2 There is no anastomosis with the surrounding tissue
3 Animals stand the decapsulation without any bad effect
4 Anatomically or clinically no bad effects follow decapsulation

J H Zaaijer[3] from animal experiments with decapsulation of the kidneys and consideration of the functional value of the new-formed capsule, concludes

> Four weeks after decapsulation of the kidneys in rabbits the new capsule anastomoses have a lesser value than in the non decapsulated kidney, but locally they may have a greater value and especially on those points where the kidney was deeper incised or injured.

Thelemann[4] in a summary on decapsulation of the kidneys made experiments with animals and comes to the following conclusions.

> The decapsulation of the kidney does not effect a pernicious influence on the parenchyma of the kidney A new capsule is formed in a short time Whether the vascularization of the new formed capsule is increased or not cannot be definitely decided In the milder cases recovery ensues, the serious cases end fatally

Prof R Harrison in his original paper preferred incision to decapsulation as it appeared to be more rational and was followed by better results I presented the same views[5] in a later communication on the same subject In support of this, M Zondek[6] in discussing decapsulation and scarification of the kidney at its clinical value proposes the scarification as superior to decapsulation He makes slight incisions in the capsule and cortex and recommends this operation for hematogenous abscesses

The observers thus far cited in relation to the histologic influence of decapsulation or incision on the kidneys do not find any harmful effect on the kidneys and the evidence furnished by animal experiments seems to show in an affirmative way that results of a beneficial nature may be effected at a time when a decompression of the kidneys may be necessary, even if it is shown histologically that the capsule is restored practically to its former condition

In opposition to the above citations, Stern[7] of Dusseldorf writes of changes in the kidney after removal of the capsule From experiments with animals the following are his findings

> Six or seven days after the decapsulation of the kidneys in rabbits, the connective tissue shows a new growth in a broad layer Kidneys injured by the operation showed deep scars in the tissue In two cases at autopsy a strong connective tissue layer was noticed in place of the removed capsule In serial section, microscopically a transition of capsule into renal vessels, as assumed by Edebohls, could not be found The primary disease in the one case was interstitial, in the other, probably luetic, nephritis was more developed in the decapsulated kidney than in the non decapsulated

Stern considers it his duty to dissuade practitioners from this decapsulation, according to his experiments with clinical subjects in cases inclining to new formations of connective tissue In other cases of nephritis the lessening of pressure on the kidney may cause an improvement, but the total decapsulation has yet to be determined Stern also says that changes occur in the kidney after removal of the tunica propria He reports from animal experiments that no cure was effected, improvement was observed in three cases, but the animals died in eight weeks and the others two weeks after the operation

These experimental and pathologic observations are helpful in predicating the class of cases in which a decapsulating operation should be made, but the final determination must be based on clinical results My own opinion is that we shall find that experimental findings and clinical results will run very close together To reach some definite conclusions in relation to the value of decapsulation of the kidneys in certain forms of kidney disease, a very voluminous literature was examined What has been written on this subject was quite beyond my expectations and it is quite possible that not a little has been overlooked, and some perhaps duplicated

The study of the literature on decapsulation of the kidneys quickly shows that a consideration of the nature of the lesion in the kidney is of the utmost importance in determining the value of decapsulation The almost uniform failure to produce any good results in chronic degenerative changes of the kidney led me, as far as possible, to classify the diseases under heads which might include affections of the kidneys in relation to which an argument could be offered in favor of the operation

DECAPSULATION OF THE KIDNEY IN ECLAMPSIA

I have undertaken first to present such arguments as the literature furnishes on decapsulation of the kidney in eclampsia I feel warranted in bringing this branch of the subject before this Section in view of the fact that there does not appear to be any line of demarcation between the effects of the operation on kidneys of a patient suffering from eclampsia and those of a patient suffering from any acute congestion of these organs, and that, so far as our knowledge goes, the benefit derived is from the immediate relief of congestion

Sippel[8] concludes that decapsulation does not exert a direct vasodilating effect, it presumably relieves a certain pressure on the veins and thus improves circulation and diuresis Sippel[9] also says in relation to decapsulation and splitting of the kidney in eclampsia that in toxic kidneys decapsulation alone is sufficient If the internal pressure be much increased a splitting of the kidney may be necessary, according to the degree of tension Sippel assumed that the escape of the edematous fluid from decapsulation restores the circulation in these capillaries Gminder[10] doubts the correctness of this theory because the escape of such a serum has never been observed Nicholson[11] is also of the opinion that decapsulation drains blood directly from the engorged venous plexuses of the anuric kidney and that this relief in the venous counterpressure promptly starts an influx of more arterial blood Falgowski found that the relief of intracapsular tension hastened resorption of accumulated inflammatory exudate on account of the resulting arterial hyperemia and restitution of the damaged secreting epithelium with the reestablishment of normal circulatory conditions Petri[12] is of the opinion that decapsulation relieves an existing congestion and furthers the elimination of detached epithelia or other substances obstructing the canaliculi

Gavriloff[13] from animal experiments with decapsulation of the kidneys in eclampsia and other affections of the kidneys concludes

1 Diuresis of the decapsulated kidney is increased.

2 The vesicular circulation in a decapsulated kidney is freer and stronger

3 The diuretic action is better in a decapsulated kidney than in a non decapsulated kidney

Ehrenfest[14] holds that according to our present physiologic knowledge such a disturbance in the circulatory conditions of the capillary system influences the secretory function chiefly only qualitatively and not quantitatively At present, however, the assumed value of decapsulation still rests solely on the belief in its specific diuretic effect Ehrenfest[14] from experiments with dogs concludes that decapsulation of the kidneys in eclampsia does not increase secretion of urine, and that there is no real ground for the belief that decapsulation is of benefit in post-partum anuria This skeptical attitude does not apply to certain cases of nephritic kidney in which Ehrenfest holds that the operation may create conditions favorable for the final restoration of structural lesions which have not progressed so far that they are beyond the possibility of repair

Ernst Runge[15] says that a definite conclusion as to the value of decapsulation in eclampsia cannot now be drawn, that the prognosis is not very favorable In desperate cases the operation may be performed by skilful hands Sippel[8] agrees that if other means fail and attacks and coma continue after delivery decapsulation is indicated Zangemeister[16] says that decapsulation of the kidneys in eclampsia is unwarranted.

A Cordero[17] reports a case of decapsulation of a kidney which was removed a year later for nephralgia The capsule was completely new formed but contained some thin vessels, which proves that a part of the new-formed vessels exist for some time as a result of the decapsulation, certainly not less than a year If the newly formed capsule is very thick in the beginning it decreases later

D Newman,[18] in a paper on "Increased Vascular Tension in the Kidney as a Cause of Renal Pain, Hematuria and Albuminuria," holds that increased vascular tension is due to two causes, the first of which is mechanical, and the second some morbid processes

M Zondek[6] in a paper read before the Berlin Medical Society, Dec 21, 1910 holds that the capsule covering the kidney is rich in elastic tissue and permits swelling of the kidney under varied conditions of the circulation, also that, if the kidney is decapsulated, the new-formed capsule is of firm connective tissue, capable of stretching, and therefore the kidney may be in serious danger in its future functionating Zondek believes that all of the immediate advantages of decapsulation can be gained by incision to the capsule without any of the dangers of decapsulation

I have found reports of ninety-two cases with definite results, given from forty-four different operators Sixty-two of the ninety-two patients recovered, thirty died, giving a mortality of about 33 per cent I have been able to ascertain that about 30 8 per cent of all cases of eclampsia, under any treatment, end fatally I cannot give any fair comparison of statistics for the reason that only in apparently desperate cases was operation performed and we are left almost entirely to individual experiences for conclusions as to the merits of the procedure, it necessarily follows that no one operator will have any considerable number to report

Alsberg[19] reports four cases of eclampsia treated by decapsulation. Three of the patients recovered and one died eight days after operation from pneumonia This latter case was included among the fatal cases, perhaps unfairly Alsberg states that diuresis was increased in every case after decapsulation

Aubert[20] reports a case of puerperal eclampsia and kidney decapsulation after normal pregnancy and delivery On the sixth day of the puerperium the patient was taken with eclampsia without previous symptoms, she had thirteen attacks during twenty hours Decapsulation of both kidneys was done The attacks did not recur and the patient recovered Aubert advises immediate operation before complications occur

Robert Asch[21] reports the case of a patient who recovered after a decapsulation and says

> If the eclampsia is severe, expectant treatment is unwarranted If delivery has not yet taken place we may await the effect of artificial delivery or cesarean section

Baumm,[22] after a successful decapsulation for eclampsia, thinks favorably of the operation and will repeat it on the next opportunity Baumm,[23] another observer by the same name, reports four decapsulations for eclampsia and does not think well of it He says "This operation does not affect the activity of the kidneys and does not cure eclampsia"

Bollenhagen[24] reports a recovery after decapsulation and observes that the decapsulation was warranted on account of the almost complete anuria

S Cholmogoroff,[25] after a fatal case, observes

> Another patient was being prepared for decapsulation when the symptoms ceased and the patient recovered without operation, if any operation had been performed with recovery of the patient, the recovery would have been ascribed to the operation

Essen-Moller[26] appears to think it doubtful whether this operation should be recommended in obstetric therapy

R Franz[27] believes that decapsulation for eclampsia is not indicated before delivery is expected, but if coma and attacks continue, the decapsulation must not be delayed

Vincent[28] reporting six cases, five recoveries and one death after decapsulation, says that the mortality without decapsulation of the kidneys in eclampsia is not greater than with it and considers the operation unwarranted

H Croom after reporting a successful case and after citing twenty-six cases with good results, recommends the operation highly

ABSTRACT OF DISCUSSION

DR. A C WOOD Philadelphia Although skeptical as to [illegible] value of this operation at first, I have become convinced that in certain cases it is [illegible] greatest [illegible] In this connection I desire to refer particularly to one case. It was that of a boy aged 1[illegible] with [illegible] nephritis and extreme general edema under the care [illegible] Prof. James Tyson of the University Hospital Philadelphia [illegible] all medical measures had been exhausted without benefit [illegible] Dr. Tyson's [illegible] I decapsulated both kidneys [illegible] of urine in twenty [illegible] during the next twenty [illegible] the quantity increased [illegible] or 12 ounces, and the day after there was another marked increase and so every day the urine increased in quantity until there was almost a [illegible] The [illegible] and the boy rapidly [illegible] when I heard from [illegible] months ago he was [illegible] at the carpenter's trade Dr Tyson informs me that [illegible] free from albumin and [illegible] and is doing a full [illegible] This case was observed [illegible] th great [illegible] persistently prior to operation [illegible] immediately after the [illegible] The case was reported by Dr Tyson in the [illegible] *of the Association of American Physicians* [illegible]

DR. LOUIS E SCHMIDT [illegible] case which was demonstrated before the [illegible] Association in Chicago [illegible] of hematuria that had existed for [illegible] very careful [illegible] operated on one side and [illegible] [illegible] found [illegible] about a year ago [illegible] some [illegible] I shall [illegible] no [illegible] hematuria continued I found a kidney comparatively normal in size, but with a great many marked retractions of the capsule I made a decapsulation in this case, and the result seems almost incredible The hematuria immediately stopped; that is, hardly any microscopic blood could be found on the first day, and practically none after the third or fourth day, and no blood macroscopically at any time since There had been no kidney elements in the urine The patient is still under observation He has a markedly low blood pressure I removed a piece of the kidney large enough for microscopic examination, and it simply showed a chronic interstitial nephritis *It seems strange, however, that there had been no kidney elements present during the course of the bleeding and none since operation*

DR VICTOR VECKI, San Francisco *My experience with the operation is not very encouraging as to curing any kind of a kidney disease, but I consider it indicated when prolongation of life is desirable I remember one case in particular, a woman who had had trouble with her husband and was involved in divorce proceedings There was a matter of a small fortune for a child, and it was really necessary that that woman should live a little longer The day she was taken to the hospital she passed only 4 ounces of urine After the decapsulation the amount of urine began to increase considerably She finally passed 2[illegible] ounces of urine, and kept on doing [illegible] for several months Ultimately, she died, as was expected, about [illegible] and seven days after the operation I [illegible] that [illegible] the operation [illegible] I have performed the operation [illegible]* [illegible]

DR. [illegible]

RECENT ADVANCES IN OUR KNOWLEDGE CONCERNING THE CAUSES OF GLYCOSURIA*

THOMAS B FUTCHER, M B
Associate Professor of Medicine, The Johns Hopkins University
BALTIMORE

Our views concerning carbohydrate metabolism in health and disease are constantly changing New facts are gradually being added to our knowledge of the subject In attempting to explain the causes of diabetes we have been forced to abandon various theories in succeeding decades The accumulated results of innumerable investigators may make obsolete to-day a theory which seemed to hold good yesterday Profiting by this experience, we must ever bear in mind that we should not be carried away by any new theory that is advanced to explain diabetes, even though it may be based on accurate experimental research

In all cases of diabetes, with the exception of the experimental phlorizin diabetes, it is generally conceded that the appearance of the sugar in the urine is dependent on the existence of a hyperglycemia It has generally been held that the glucose content of the blood normally ranges between 0 1 and 0 2 per cent, although Jacobson, working under Cushing's direction in the Hunterian Laboratory at the Johns Hopkins University, believes that these figures are too high and that the normal content is approximately 0 08 per cent Undoubtedly some regulatory mechanism controls the glucose content of the circulating blood, for in the healthy individual it is found that, even after a meal rich in carbohydrates, the percentage of glucose in the circulating blood remains within very narrow limits The carbohydrates in the food are stored up after a meal in the liver and muscles in the form of glycogen Glycogen is believed to be gradually reconverted again into glucose and given up to the tissues as they need it for the production of heat and energy Whenever the glucose content of the circulating blood rises above the physiologic limit a hyperglycemia results and the excess then passes over into the urine and produces either a transitory glycosuria or a permanent glycosuria, as in true diabetes mellitus.

The explanation of a transitory or a permanent glycosuria therefore rests on the determination of the cause or causes of the hyperglycemia An excess of glucose in the circulating blood may be conceived as occurring in one of two ways 1 It may be due to an overproduction of glucose from the glycogen of the liver 2 It may be due to an inability of the tissues, particularly the muscles, to destroy the glucose, or, in other words, to defective oxidation Each of these theories has been supported by able investigators in the past, but the trend of opinion at the present time is in favor of the overproduction theory

THE RELATIONSHIPS OF THE DUCTLESS GLANDS TO CARBOHYDRATE METABOLISM

Investigations in recent years have shown that the internal secretions of the ductless glands have a marked influence on carbohydrate metabolism in health and disease The internal secretions which have been shown up to the present to possess this relationship are those of the pancreas, adrenals, thyroid, parathyroids and pituitary Strictly speaking, the pancreas is not a ductless gland, but it incorporates within its substance the islands of Langerhans, which are really ductless glands According to our present knowledge, it is in these islands that the internal secretion of the pancreas which so strongly influences carbohydrate metabolism is produced It may be shown later that other ductless glands, such as the thymus, ovary, etc, must be added to the list. The function of influencing carbohydrate metabolism is only one of the numerous activities each of these glands is known to possess

As Cammidge[1] recently said in a most interesting article bearing on this subject, "It is now believed that chemical correlation and chemical control exists between practically every gland and tissue of the body" It has been possible, in some instances, to isolate the specific chemical activator or "hormone" through which one tissue activates another It has been shown by Bayliss and Starling[2] that the hydrochloric acid secreted by the stomach acts on the mucous membrane of the upper part of the intestine and gives rise to a substance to which they have given the name "secretin" The latter, when absorbed into the blood, travels to the pancreas and stimulates it into functional activity and causes a flow of its secretion Other similar examples might be cited

THE INTERRELATIONSHIP OF THE ACTION OF THE DUCTLESS GLANDS

It will be of interest to discuss at this point the noteworthy results of Falta, Eppinger and Rudinger[3] who have devoted special attention to the study of the interrelationship of the action of the internal secretions of the ductless glands They believe that the removal of a gland with an internal secretion works in two ways There is, first, the direct result of the absence of its secretion, and secondly, the indirect effect due to the disturbance of metabolism consequent on its relations to other glands They hold that the ductless glands may be divided into two groups according to the disturbances of the metabolic functions of the body to which alterations in their secretory activities may give rise They divide them into (1) an accelerator group and (2) an inhibitory group To the accelerator group belong the thyroid, the adrenals and the hypophysis, since it has been shown that a study of the reactions of the body to injections of preparations from these organs and observations on the result of experimental interference with their functions suggest that all three increase protein exchange, the adrenals cause mobilization of carbohydrates, and the thyroid causes increased fat destruction To the inhibitory group belong the pancreas and parathyroids, because it has been shown that both retard protein destruction, the pancreas being the more active, further, both restrain the mobilization of carbohydrates, the pancreas again being the more active of the two The pancreas also causes a decrease in fat consumption These investigators have correlated their results and have come to the following conclusions

1 The internal secretions of the thyroid and pancreas mutually retard each other's activities

2 The internal secretions of the pancreas and chromaffin system mutually retard each other's action

3 The internal secretions of the thyroid and chromaffin system mutually increase or accelerate each other's action

In explanation it may be said that the chromaffin system has reference to those groups of cells which have a particular affinity for the salts of chromic acid These cells are found chiefly in four situations (1) they occur in the adrenals, where the largest collection of such cells occurs, (2) they accompany the nerves of the sympathetic system, (3) they occur in abundance in the retroperitoneum, (4) they are grouped together in the pelvis to form the so-called Zuckerkandl organ For all practical purposes, the word "adrenals" may be substituted for "chromaffin system" in the above classification of the accelerator and inhibitory activities of the internal secretions of the ductless glands

THE RELATIONSHIP OF THE PANCREAS AND ADRENALS TO CARBOHYDRATE METABOLISM

Owing to the intimate relationships that are now believed to exist between the internal secretions of the pancreas and adrenals and carbohydrate metabolism the functions of these two glands will be considered together

Although a relationship between the pancreas and carbohydrate metabolism had been suspected for nearly a century, it remained for von Mering and Minkowski[4] to demonstrate in 1889 that complete removal of the gland in dogs was invariably followed by a fatal diabetes, with practically all the features as observed in severe cases in man They subsequently showed that the diabetes was not dependent on the loss of the external secretion of the glands but rather on the absence of some internal secretion which is poured directly into the blood- or lymph-stream

Lepine believed that this internal secretion was of the nature of a "glycolytic ferment," whose presence in the circulating blood was necessary for the proper combustion of the glucose of the blood

In 1900 Opie found that a certain percentage of cases of chronic interstitial pancreatitis were accompanied by diabetes Histologic examination of the pancreas in all cases in which the gland was sclerosed showed that glycosuria occurred only in those cases in which there was extensive destruction of the islands of Langerhans Later Opie showed that many cases of diabetes with apparently normal-looking glands macroscopically showed on microscopic examination extensive hyaline degeneration of the islands of Langerhans This important observation led to two natural inferences first, that the internal secretion of the pancreas which influenced carbohydrate metabolism was probably produced by the islands of Langerhans, and second, that it might subsequently be shown that many if not all cases of diabetes would probably be found to be due to degenerative changes in the islands of Langerhans Subsequent investigations have shown that there are many cases of diabetes which cannot be explained in this way, for it has been found that in certain cases of diabetes the islands are intact

The publication of Cohnheim's[5] experiments in 1903 seemed to afford a satisfactory explanation as to how the carbohydrates are utilized in the body under normal conditions and by inference gave us an explanation of the cause of diabetes According to his view, in order that carbohydrate metabolism should be properly carried on, it was necessary that some substance in the muscle juice be activated by a hormone contained in the internal secretion of the pancreas If for any reason this pancreatic hormone be lacking the glucose would not be utilized in the muscles and would accumulate in the circulating blood, producing a hyperglycemia and a consequent transitory or permanent glycosuria Although Cohnheim's views were hailed with enthusiasm they have not been universally accepted It is quite possible that there is some interaction between the internal secretion of the pancreas and muscle juice, which results in the production of a substance which favors the combustion of carbohydrates More light, however, needs to be shed on this phase of the subject

Although the influence of the internal secretion of the pancreas on carbohydrate metabolism cannot be questioned, its method of action, as we have already seen, is uncertain There is a growing belief that the internal secretions of the pancreas and adrenals are complementary to one another and that each exerts its influence on carbohydrate metabolism by regulating the formation of glucose from the glycogen of the liver

Zuelzer[11] is responsible for the theory, now possessing many adherents, that the internal secretion of the adrenals influences carbohydrate metabolism by "mobilizing" the carbohydrates of the body, particularly of the liver In other words, unless its action is counteracted, the function of the internal secretion of the adrenals is to set free the carbohydrates of the liver and other tissues, causing a hyperglycemia with consequent glycosuria Zuelzer further showed that an antagonistic action exists between the adrenal secretion and the internal secretion of the pancreas

Zuelzer thinks that the internal secretions of the adrenals and pancreas normally react on each other within the liver in such a way as to maintain the normal sugar production from the glycogen and consequently glycosuria is prevented As Falta, Eppinger and Rudinger[3] have shown, the internal secretions of the pancreas and adrenals mutually retard the action of each other Thus, when Zuelzer used the liver of a depancreatized dog, the output of sugar in the urine was increased because there was no pancreatic secretion to retard the "mobilizing" action of the adrenal secretion on the glycogen of the liver In the second experiment, in which the liver from a dog with adrenal diabetes was used, the further increase in the sugar output was due to the "mobilizing" action of the epinephrin that had been used in inducing the adrenal diabetes He further found that when the function of both the adrenals and pancreas was destroyed glycosuria failed to occur In the depancreatized dog he found that glycosuria did not occur if the adrenal veins were ligated In a large number of pancreatectomies performed by Zuelzer, glycosuria always followed except when the adrenal veins were also tied off He believes that one of the most important functions of epinephrin is its influence on sugar metabolism in the liver

Accepting for the time being this view of carbohydrate metabolism, the hyperglycemia in pancreatic diabetes is believed to be due to the absence of the restraining hormone normally produced by the pancreas The "mobilizing" action of the epinephrin consequently causes an overproduction of sugar in the liver with resultant excess of glucose in the circulating blood followed by the inevitable glycosuria

Undoubtedly the nervous system has a marked influence on carbohydrate metabolism Owing to the intimate relationship that is known to exist between the sympathetic and autonomic nervous systems and the chromaffin system it is easy to conceive how psychic disturbances and disturbances particularly of the autonomic system can stimulate the chromaffin system and cause an overproduction of the internal secretion of the adrenal glands, leading to a "mobilization" and overproduction of glucose in the liver and other storehouses for carbohydrates This would lead to hyperglycemia and glycosuria It was formerly thought that the glycosuria that resulted from Claude Bernard's puncture of the floor of the fourth ventricle was due to direct stimulation of the liver through its nervous connections It has been found, however, that if the left adrenal is cut off from the left sympathetic nerve, no sugar appears in the urine after the medulla has been punctured, and it is now believed that the stimulus is transmitted by the left sympathetic nerve to the left adrenal, whence it is passed to the right adrenal by the connecting nerves As a consequence of the medullary puncture the adrenals secrete more actively and the increased flow of the adrenal secretion in its turn brings about an excessive output of sugar by the liver A number of toxic influences possibly act in the same way, the glycosuria to which they give rise being partly the result of the action they exert on the diabetic center in the medulla, and partly an effect of their stimulating action on the sympathetic nerves, or on the adrenals directly, thus, in any case, causing hyperfunction of the chromaffin system, with consequent overproduction of sugar by the liver

THE RELATIONSHIP OF THE THYROID AND PARATHYROIDS TO CARBOHYDRATE METABOLISM

Every observer who has had a wide experience with diseases of the thyroid gland has been impressed with the fact that in hyperthyroidism and hypothyroidism there is a marked disturbance in carbohydrate metabolism Kraus, Ludwig, Chvostek and many others have observed that spontaneous glycosuria is not uncommon in exophthalmic goiter Further, it has been shown that the administration of small amounts of carbohydrates in this condition often causes a temporary glycosuria In other words, in overactivity of the gland the tolerance for carbohydrates is reduced

On the other hand, in hypothyroidism, myxedema, the occurrence of spontaneous glycosuria is so rare as to practically never occur

THE RELATIONSHIP OF THE PITUITARY TO CARBOHYDRATE METABOLISM

We are chiefly indebted to Cushing[18] and his associates for the demonstration in the last few years of the fact that the pituitary gland contains in its internal secretion a hormone that has a powerful influence on carbohydrate metabolism It is thought that one of the functions of the pituitary glands is to preside over the regulation of carbohydrate tolerance It will be impossible here to give a description of the gross and histologic anatomy of the pituitary gland, but it may be of interest to enumerate the important functions that have been demonstrated to be possessed by its two lobes

I FUNCTIONS OF THE ANTERIOR LOBE

1 It influences body growth If a hypersecretion (hyperpituitarism) occurs during the years of the individual s growth, gigantism results If the hyperactivity occurs after the individual s full growth has been attained then acromegaly results If a diminished secretion (hypopituitarism) occurs, a form of infantilism results, to which attention was first drawn by Fröhlich This condition is known as Fröhlich's syndrome, or "dystrophia adiposa genitalis" It is characterized by small stature, amenorrhea in women, infantile genitalia in both sexes, hypotrichosis, excessive deposition of fat and increased carbohydrate tolerance

2 Injections of extract of the anterior lobe cause an increase in temperature

3 Extract of the anterior lobe increases thyroid function

II FUNCTIONS OF THE POSTERIOR LOBE

1 Its extract causes an increase in blood pressure

2 It is a powerful diuretic

3 It has a remarkable influence over carbohydrate metabolism

4 Schaefer and Vincent think it also contains a substance which may lower blood pressure

5 Rinon and Delille think that the extract stimulates the function of the adrenals and lessens that of the thyroid

It is most interesting that the hypophysis, which previous to two decades ago was considered without function, has now been shown to possess so many important properties Cushing has shown in dogs that the gland is essential to life, for complete removal of the gland invariably results in death It is believed that it is the anterior lobe that is necessary to life, for its removal alone will produce death Cushing holds that the secretion of the pituitary passes by way of the infundibulum into the cerebrospinal fluid in the third ventricle, for he has shown that death also occurs if the hypophyseal stalk is excised while the gland is left behind

It is the influence which the pituitary secretion of the posterior lobe has on carbohydrate metabolism that concerns us most here It was Cushing and his co-workers who first demonstrated by partial hypophysectomies on dogs that it is the posterior lobe of the pituitary which influences carbohydrate tolerance It has now been definitely shown that hyperpituitarism, clinically represented by gigantism and acromegaly, is nearly always accompanied by a lowering of the individual's tolerance for carbohydrates resulting frequently in either a transitory or permanent glycosuria On the other hand, hypopituitarism, clinically represented by the various types of pituitary infantilism, is practically always accompanied by an enormous increase in the tolerance for carbohydrates, so that the patient can ingest from two to five times the amount of glucose and other sugars that a normal individual can without alimentary glycosuria occurring

It was in 1889 that Marie first pointed out the association of acromegaly with pituitary enlargement, although he had described the disease in 1886 Since 1889 there have been numerous reports of cases in which glycosuria has been found in association with acromegaly Out of 176 cases of the disease reported in the literature up to 1908, Borchardt found that glycosuria occurred in 35 5 per cent of the cases Cushing comments on the discordant results which different observers have found in the study of carbohydrate tolerance in acromegaly Some observers have found an actual glycosuria, others only a diminished tolerance, and still others a decidedly increased tolerance Cushing is of the opinion that these discrepancies are entirely dependent on the stage of the disease in which the case comes under observation He holds that the adenomas or other tumors of the anterior lobe of the pituitary, which cause the characteristic features of acromegaly, also produce hyperplasia and overactivity of the posterior lobe in the early stages (hyperpituitarism), with the result that an excess of the secretion reaches the circulation and a lowered tolerance to carbohydrates ensues In the later stages a hypoplasia with consequent destruction and lack of secretion of the posterior lobe occurs (hypopituitarism), with the result that there is an increased tolerance to carbohydrates

CONCLUSIONS

1 It is unwise, from past experience, to accept as settled any new theory advanced to explain the cause of diabetes mellitus

2 It must now be accepted as positively proved that not only the pancreas but also the adrenals (chromaffin system), thyroid, parathyroids and pituitary have a very important influence on carbohydrate metabolism

3 Although lesions of the pancreas have been found in a considerable percentage of cases of diabetes, it is now clear that morbid changes in that organ will not explain all cases, even when alterations in the islands of Langerhans are also taken into account The essential and primary disturbance may be in one or another of the ductless glands

4 There is undoubtedly a marked correlation of the internal secretions of the ductless glands Thus the internal secretions of the adrenals (chromaffin system) and pancreas mutually retard the action of each other The most recent theory concerning carbohydrate metabolism is that first advanced by Zuelzer and now supported by many physiologists According to this view, one of the important functions of the adrenals is to "mobilize" or set free the carbohydrates in the liver and possibly in other storehouses also Under normal conditions, however, this influence is counteracted or exactly balanced by the hormone contained in the internal secretion of the pancreas, and we have a constant normal flow of sugar from the liver When, however, the chromaffin system is for any reason overstimulated, as it may be through the sympathetic nervous system, there is an overproduction of the "accelerator" hormone of the adrenals, the "retarding" hormone of the internal secretion of the pancreas is more than counterbalanced, the glycogen in the liver is rapidly "mobilized" or set free and a hyperglycemia and glycosuria result. A similar result occurs in the cases of so-called pancreatic diabetes Here the adrenal hormone may be normal in amount, but owing to the pancreatic disturbance the pancreatic hormone is absent or diminished and again the adrenal hormone is enabled to mobilize the glycogen of the liver

5 A somewhat analogous explanation may subsequently be found to explain the glycosurias in pituitary and thyroid diseases

6 The theory that hyperglycemia results from deficient consumption or oxidation of glucose in the tissues has fewer adherents than formerly It may still be shown, however, that Cohnheim's theory is in part correct At present the trend of opinion is in favor of the view that the hyperglycemia and glycosuria are dependent on overproduction of sugar in the liver as expressed under Conclusion 4

ABSTRACT OF DISCUSSION

Dr Robert T Morris New York In some cases of "gall stones without symptoms" glycosuria is the chief symptom After removal of a gall stone or drainage of a septic gall bladder the glycosuria ceases One of our best known New York surgeons suffered from lumbago for years and was incapacitated for work a large part of the time by a glycosuria, when gall stones were removed the lumbago and glycosuria ceased This relationship between glycosuria and gall stones we have assumed to be due to influence on the islands of Langerhans by the gall stones, the reflex irritation causing a congestion of the pancreas to the point of lessened efficiency Is that the correct view, or is a toxic impression made on the pancreas by an infected gall bladder neighbor?

Dr Emil Goetsch, Baltimore In a paper published together with Drs Cushing and Jacobson in the *Bulletin of Johns Hopkins Hospital*, June, 1911, some facts were pointed out concerning carbohydrate metabolism in hypophysectomized animals, and its relationship to the posterior lobe secretion The manner of hitting on these facts was interesting I was studying the growth of dogs after hypophysectomy, and noticed that in cases of total or "near total" removal of the pituitary body there was produced frequently a transient glycosuria, which appeared almost immediately after the operation and disappeared in two or three days This was inexplicable until we began to test the carbohydrate tolerance of these animals before and after operation It was found that after removal of the hypophysis either "near total" or even of the posterior lobe there was found invariably an almost immediate great reduction in the carbohydrate tolerance to a point often of spontaneous glycosuria, to be followed in the course of about ten days by recovery of the normal tolerance and then a gradual increase during a period of a week or two more until the tolerance reached often to double the normal Cane sugar and glucose were used both by mouth and intravenously in these tests It was found also that we could reduce this overtolerance by injecting intravenously or hypodermically extract of hypophysis A comparable action was found to exist in the thyroid gland indicating a similar influence of these two glands at least on some features of carbohydrate metabolism It is still an open question as to how the pituitary secretion (posterior lobe) exerts this influence We felt that it was possibly due to some influence on the pancreas or liver For example we found that after hypophysectomy the liver cell was filled with fat, there was an apparent transformation of glycogen into fat with storage of the latter Oxidative processes in the body were also low There was frequently subnormal temperature which could be made to rise until a definite febrile response of 3 or 4 degrees could be obtained Then, also, in a number of clinical cases with hypophyseal disease a hyperglycemia was observed These are a few of the facts concerning hypophyseal activity which bear very closely on the problems of glycosuria as brought out by Dr Futcher

Dr. T B Futcher, Baltimore I am not prepared to give an explanation of the manner in which glycosuria is brought about by an attack of gall stone colic. Two possible explanations are conceivable One is that there may be some direct effect on the liver itself, causing it to give up the glycogen in the form of glucose, or it may exert its effect through the sympathetic nervous system, which we know is so intimately associated with the chromophilic system and the adrenals, and there may be at the time a hypersecretion of the adrenals which leads to a mobilization of the carbohydrates in the liver with resultant hyperglycemia Whether that is the explanation or not, I cannot say

It was demonstrated in 1850 that puncture of the fourth ventricle led to a temporary glycosuria Claude Bernard believed that the glycosuria was due to certain impulses sent to the liver More recent work has shown that that explanation is probably not true If one severs the nerves going to the left adrenal, a hyperglycemia does not follow the medullary puncture The latest explanation for the glycosuria that follows certain traumatisms and fractures of the base of the brain is that impulses are sent out by way of the sympathetic system to the left adrenal, and thence to the right adrenal, causing a hypersecretion which mobilizes or sets free the glycogen of the liver producing a hyperglycemia and transitory glycosuria

THE SURGICAL TREATMENT OF CHRONIC SEMINAL VESICULITIS BY VASOSTOMY (BELFIELD OPERATION)*

ROBERT H. HERBST, M.D
CHICAGO

In discussing the surgical treatment of chronic seminal vesiculitis it might be well to consider briefly the bacteriology of this condition The bacteria commonly found producing pathologic changes in the seminal vesicles are the gonococcus, staphylococcus, streptococcus, tubercle bacillus and colon bacillus Although the gonococcus is by far the commonest cause of seminal vesiculitis, the ordinary pus-producing organisms, namely, the staphylococcus and the streptococcus, not infrequently produce an inflammation of the vesicles It is in these latter cases that faulty diagnoses are commonly made, especially if they happen to occur in old men, or in those who do not give a history of a recent gonorrhea The tubercle bacillus may invade the seminal vesicles by way of the blood-stream, by direct extension from the upper part of the genital tract or by extension from the urinary tract

The part played by the colon bacillus in vesicle infections is not very well known, although this germ has been demonstrated as the causative agent in producing infection of the epididymis

Three distinct conditions are found in studying the pathology of chronic seminal vesiculitis

1 Cases in which the vesicle condition is complicated by a complete obstruction of the ejaculatory duct, which is attributable either to a stricture or to the duct being blocked by detritus and exudation In this class the vesicle is virtually converted into a retention cyst

2 Cases in which there is a partial occlusion of the duct, due either to stricture or to inflammatory swelling

3 Cases in which the duct is perfectly patent and the inflammatory process is limited to the vesicle

Although there is little to be found in the literature on stricture of the ejaculatory ducts, Dr Belfield found the stricture to be unilateral in two cases and bilateral in one case in the consecutive examination of twenty-five dead-house subjects He has also demonstrated it in the living

The patency of the ejaculatory ducts seems to me to be a most important point in the choice of treatment for seminal vesiculitis The common symptoms of this condition, such as a gleety discharge, pain low down in the pelvis and during ejaculation, are well known, but there are many cases in which these symptoms are not pronounced and in which the patient has symptoms which we are likely to refer to the bladder or the prostate Given for example, a man advanced in years, who complains of frequent and imperative urination, with probably some enlargement of the prostate gland, we not infrequently class him as a prostatic when, in reality, he is suffering more from an inflammatory condition of the seminal vesicles rather than from the prostate gland

Several times in my limited experience it has been my good fortune to have relieved by vasostomy and lavage of the seminal vesicles patients, who were supposed to be suffering from hypertrophy of the prostate, and on whom prostatectomy had been advised In certain cases, too, vasostomy has relieved symptoms ascribed to an enlarged prostate, just as did castration years ago Frequently during the first twenty-four hours after performing a vasostomy, a patient who, before the operation, had been tormented by frequent and imperative urination and the usual so-called colic of the neck of the bladder is completely relieved of his symptoms I think that the explanation of this prompt relief lies in the fact that, by opening the vas, we place the seminal vesicle at physiologic rest This also probably explains why improvement was observed in certain cases of hypertrophy of the prostate when castration had been performed, in other words, those patients who improved after castration were suffering from disease of the vesicles rather than from disease of the prostate

Probably one of the most important points in the treatment of chronic seminal vesiculitis by vasostomy is the proper differentiation of cases It is obvious that not all cases of vesiculitis require surgical interference, also that drainage of the vesicles by making an opening in the vas deferens is not possible in all cases From a therapeutic standpoint, it might be well to make the following classification

Class 1 Cases of chronic seminal vesiculitis in which the ejaculatory ducts are perfectly patent

Class 2 Cases in which there is an atresia or partial occlusion of the ducts

Class 3 Cases in which there is a complete obstruction of the ducts

Class 4 Cases complicated by stricture of the vas deferens high up

The cases in Class 1, namely, those having patent ejaculatory ducts, can easily be selected, owing to the fact that they can be readily emptied by pressure of the examining finger in the rectum Most of these cases will respond to stripping and instillations and do not require any operative interference

The cases in Classes 2 and 3, in which there is either a partial or a complete occlusion of the ducts, are those in which the only hope for cure lies in some operative measure — vasostomy, incision or excision of the affected organ During the last few years I have completely abandoned the method of stripping the vesicles in all cases in which they do not readily empty on pressure in the rectum over the vesicles I believe that failure of the vesicles to empty on pressure in the rectum is usually an indication that there is either a partial or a complete occlusion of the ejaculatory ducts, and that stripping of such a vesicle will force the infected contents into the vas, which is commonly followed by an epididymitis.

Vasostomy is also a valuable measure in the prevention of recurring attacks of acute epididymitis Patients in this condition sometimes feel distress and pain along the inguinal canal and the region of the external ring, even before the epididymis is infected An opening into the vas at this time may succeed in preventing a subsequent infection of the epididymis

In cases of Class 4, in which there is a stricture high up in the vas, it is perfectly clear that one could not hope to obtain either drainage or lavage of the vesicle, because the obstruction is proximal to the opening in the vas These cases, however, are comparatively rare Aschoff, in the examination of one thousand subjects, found unilateral stricture of the vas deferens in seventeen cases and bilateral in six cases.

The simplicity of technic in vasostomy indicates it as the operation of choice when surgical measures are deemed necessary for vesiculitis The technic of vasostomy is too well known to require description There are, however, two points that might be emphasized

---

* Read in the Symposium on Genital Pathology and Surgery in the Section on Genito Urinary Diseases of the American Medical Association at the Sixty Third Annual Session held at Atlantic City June 1912.

1 The vas should be well fixed against the posterolateral wall of the scrotum before the initial incision is made

2 The vas should be entirely stripped of its sheaths before incising it

These precautions will assist one in finding the lumen of the vas for subsequent injections into the vesicles In cases in which the indications for a vasostomy have been correctly observed, the results are uniformly good The question as to whether the vas deferens is patent after a vasostomy may arise in the minds of some There is very little reason why the tube should not remain patent when we reflect that the incision into the vas is a small longitudinal one I am satisfied that strictures following this operation are rare, as I have had opportunities of examining the semen of five of my patients with bilateral stricture and have found spermatozoa in all of them I do not believe, however, that the question of sterility should enter into consideration, providing that the indications for the operation previously existed Knowing that the vast majority of these cases are postgonorrheal and that they refuse to respond to the old method of stripping the vesicles, and knowing, too, that these subjects are a constant menace to every woman with whom they cohabit, who in many instances is the innocent wife, it is my contention that if the vas was blocked in every man on whom vasostomy was performed the operation would still be indicated

I am satisfied that patients with postgonorrheal vesiculitis are the most common carriers of gonococci to the marriage bed, and I repeat that, if once in a large number of cases we should happen to block the vas of an individual by vasostomy, it would be far better than that he should marry with his seminal vesicles contaminated with gonococci

This report includes 104 operations on eighty-eight patients, thirty-two of my cases being bilateral, eleven were due to the ordinary pyogenic organisms, seventy-seven were of the postgonorrheal type The vas was kept open for from seven to twenty-one days Injections were made daily, in a few instances, twice a day for the first few days after operation The mild silver salts were first used and were followed by the more astringent salts Of the eighty-eight cases, fourteen passed from my control before I could ascertain results Of the eleven cases due to ordinary pus infection, ten are cured, one patient still complains of colic following urination, though he affirms that it is less severe than before the operation

I was able to control sixty-three of the seventy-seven postgonorrheal cases The gonococcus was demonstrated in the gleety discharge, in the expressed secretion from the prostate and vesicles or in the ejaculated specimen of semen In the event that the cases were complicated by a stricture, folliculitis or prostatitis, these conditions were treated before the operation was performed The duration of the postgonorrheal condition varied from three months to eight years

Many of the older cases had gone through several acute exacerbations Forty-one of the sixty-three patients were cured by vasostomy, i e, their symptoms disappeared and I was unable to demonstrate the gonococcus either in the expressed prostatic and seminal secretion or in the ejaculated seminal discharge Of the twenty-two cases that did not clear up after the operation three patients were free from gonococci but still complained of some pain and frequency of urination One of these, however, improved after a thorough course of massage of the prostate Of the nineteen cases in which gonococci were still present after vasostomy and lavage, seven cleared up after massage and instillation into the posterior urethra In twelve cases I was unable to eliminate the gonococcus It is my opinion that in some of these the gonococcus was harbored in some of the inaccessible recesses of the prostate gland

If I may be allowed to eliminate the fourteen cases that passed from my control, in fifty-one of the seventy-four cases the cure may incontestably be attributed to vasostomy which is a percentage of 67 This may not appear at first sight to be a strikingly high proportion, but if the class of cases be taken into consideration I am certain that most of them would heretofore have been designated as cases of incurable postgonorrheal seminal vesiculitis

SUMMARY

1 Symptoms referred to the bladder and prostate are frequently relieved by vasostomy

2 In certain cases vasostomy has relieved symptoms ascribed to an enlarged prostate, just as did castration years ago

3 Vasostomy is especially indicated in cases in which we have to deal with either a partial or a complete occlusion of the ejaculatory ducts

4 This operation gives a fairly high percentage of cures in a class of cases which must either be relegated to the incurable heap or be subjected to a far more dangerous and difficult surgical procedure

I take this opportunity to thank Dr Belfield for my early instruction in this work, and for his ever willing consent to the use of the material in our clinics at Rush Medical College and the Chicago Policlinic.

32 North State Street.

PARANOID TYPE OF INSANITY WITH JACKSONIAN CONVULSIONS SYPHILITIC CEREBRAL PACHYMENINGITIS, THE MICROSCOPIC FINDINGS [*]

N S YAWGER, M D
PHILADELPHIA

F C, a colored man aged 42 years, was arrested Sept 5, 1910 while sleeping in a new school building, but because of his strange statements he was taken to the psychopathic wards of the Philadelphia General Hospital, from there he was transferred to the Insane Hospital, September 9, where he developed jacksonian convulsions and died about three months later The cause of his mental state was not determined clinically

For some time previous to his detention and until he died, certain fixed delusions persisted in the mind of this patient He stated that the new school building in which he was arrested had been fixed up for him by God's orders and that it was to be called God's Angel's Temple He drank at times but he had not been drinking for several months previous to his detention at the hospital About a week after he had stopped drinking, he said he heard God call his name and say "You are free from sin, you shall live and never die, you shall never go hungry and you shall never go naked" Because of his shouting his friends thought he was crazy from drink and he was arrested, shortly afterward he became quiet and he was released After this 'call" from God he stopped work He said God talked to him both day and night and told him secrets, but what these were he would not reveal

---

[*] Read in the Section on Nervous and Mental Diseases of the American Medical Association at the Sixty Third Annual Session held at Atlantic City June 1912

[*] From the Laboratory of Neuro-Pathology of the University of Pennsylvania and the Philadelphia Hospital for the Insane

His mental examination at this time showed no disorientation, he had hallucinations of hearing, believing that he heard God's voice, his delusions were shown by his belief that the schoolhouse had been built for him by God's orders and that he was God's angel. He stated that he did not have enemies, was not possessed of much physical strength and was not wealthy, in fact, he talked sanely about all other matters.

The points of interest in his physical condition were unequal pupils, the left being slightly the larger, slight tremor of the muscles about the mouth, deviation of the tongue slightly to the left, enlargement of the inguinal glands, and several scars over the shins.

While talking to his physician, Jan. 13, 1911, he said "*I am going to have a fit, I had two of these last night,*" he then had a seizure. There was involvement of the left side of the face and left arm without any disturbance of consciousness. The convulsions of the night before were his first seizures. After this he had several isolated convulsions and on April 3, was seized by a series of fits, which involved the whole left side of the body. At one time he had 200 convulsions in sixty hours and these were followed by a left sided exhaustion paralysis. The seizures were for the most part confined to the left side and were clonic in type, but they were never attended by the loss of consciousness. A warning always preceded them and this the patient described as a peculiar sensation in his head. Plantar stimulation at times gave a Babinski response, which was present more frequently on the left side. The ophthalmoscopic examination showed no abnormality, and there were no extra ocular palsies, no persistent headache and no vomiting. The patient was at no time melancholy or violent, and his fixed delusions persisted until he died. The seizures usually appeared in series and were followed by a slight elevation of temperature, the last series occurred four days before his death; for a few days previous to this his *heart action was irregular,* his pulse was over 100 and his temperature was subnormal.

Because of the exalted delusions there was at first some thought of the psychosis being dementia paretica, paranoia also was considered. Later, when convulsions developed, it was suspected that the condition had a syphilitic basis, unfortunately the cerebrospinal fluid was not examined nor was a Wassermann test obtained and so no positive mental diagnosis was made.

AUTOPSY REPORT

The general body findings were heart, chronic interstitial myocarditis, lungs, passive congestion and subacute bronchitis, liver, fatty degeneration, slight perilobular fibrosis and chronic interstitial hepatitis, spleen, chronic interstitial splenitis, kidneys, chronic interstitial and chronic parenchymatous nephritis. These chronic findings were not more than suggestive of syphilis.

Under the calvarium, the dura in the right superior parietal region was adherent to the bone, when separated, the bone was found, roughened and reddish in color. There was no evidence of an old fracture. At this site and even extending somewhat below the right parietal region the dura was adherent to the pia arachnoid, and the superficial part of the cortex was stripped off with the membranes. The area of most extensive pachymeningitis was about 2½ inches in diameter and one third inch thick near the center, becoming thinner gradually toward the periphery. There was very slight thickening of the dura for considerable distance beyond this but the rest of the membrane was of normal thickness and texture. The surface of the lesion was somewhat irregular though not distinctly nodular; its consistency varied, being considerably firmer in some parts than in others. The pia arachnoid was somewhat congested. Beneath the area of most extensive pachymeningitis, the convolutions were somewhat flattened. The base of the brain and the vessels were normal. There was slight excess of cerebrospinal fluid, especially in the lumbar region of the cord. The weight of the brain and part of the membranes which happened to be attached was 1,372 gm. (48.4 oz.) this is but little less than the weight of the normal adult male caucasian brain and about 200 gm. (6.1 oz.) heavier than the average weight of the brain of the colored adult in dementia paretica.

HISTOLOGIC FINDINGS

The dura was thickened to perhaps three times its normal diameter but it was difficult to determine just where the dura stopped and the extra development of fibrous tissue began. Many irregularly rounded holes were seen and these probably had resulted from the hardening of edematous tissue. The development of fibrous tissue was very extensive and many of the fibers were markedly swollen. Throughout, there was a rather free leukocytic infiltration with here and there intense localization. Embryonic cells were abundant and increased vascularization was observed. Some masses of granular detritus were seen here and there, and these were probably disintegrated red blood cells.

The cellular infiltration consisted for the most part of three varieties of cells and these appeared to be lymphocytes, mast cells and plasma cells. The lymphocytes were greatly in preponderance. In some areas there were many large, round or oval, highly granular cells, their diameters ranged from 10 to 18 microns. They *mostly contained relatively large, round* or slightly lobulated nuclei which were usually eccentrically placed. When stained with theonin, these cells took on an intense blue color but under artificial light they assumed a deep purple tint, while the lymphocytes remained blue and the red blood cells showed a greenish tinge. These cells conformed more nearly to the type of the mast cell than any other with which I am familiar. The third variety of cells corresponded to the description usually given of plasma cells, they were much less numerous, usually larger and tended to be more angular than the mast cells and they contained finely granular protoplasm. In most of the sections, particularly those stained with hematoxylin, many endothelial cells were observed, these, perhaps, were due to active proliferation, but at no time were such cells found within the lumen of the vessels, often they appeared to be engaged in the formation *of new blood vessels.*

The pia arachnoid was much thickened and densely adherent to the dura. Within the meshes of the membrane there was a diffuse cellular infiltration, the vessels were increased in number with some perivascular cellular areas.

There was subpial neurogliar proliferation amounting to a dense felting, and this accounted for the superficial layers of the cortex being removed with the membranes. These neurogliar cells were very numerous and of gigantic size with many hair like processes radiating from them. Almost all stains revealed the presence of these bodies, but they were most intensely stained by Mallory's neurogliar stain and Weigert's myelin sheath stain. The cells nearest the pia were so closely interwoven as scarcely to be recognized, but as they extended farther into the cortex, their outlines and processes became clearly visible. In contrast with the commonly seen stellate glia cells, their sectional area was four or five times as great, they were mostly oval and had many exceedingly long processes, they frequently contained two or more nuclei, they were proliferating most rapidly and were seen in all stages of development.

The cortex immediately beneath the involved meninges showed some perivascular cell infiltration, but this probably had extended from the meninges. A most destructive process had gone on in the superficial cortical area. Some of the pyramidal cells were barely recognizable, many were shriveled up, others appeared as a pale blue area in which nothing definite could be observed except the nuclei, the angles of the cells were almost lost and the tigroid bodies in many places had disappeared entirely, sometimes the nuclei were not apparent, frequently they were vesicular, often they were displaced and occasionally they bulged beyond the cell outline.

The most superficial medullated fibers showed some varicosities and attenuation but elsewhere the fibers were normal. The vessels at the base of the brain were normal.

There is no specific character to a syphilitic psychosis, it may partake of the type of dementia, mania, melancholia or paranoia. Of course the same is true of an alcoholic psychosis, and since this patient drank to some extent, it is possible that alcohol played a part in causing his mental condition, but this certainly did not account for his convulsions. As to the pachymeningitis which doubtless was the cause of the convulsions. It has been said that syphilis "never attacks exclusively any small area of the brain or cord, it is never strictly local, but always more or less generalized." There was no history of traumatism in this patient nor was there any evidence of an old injury in the bone over the area involved, still, in a syphilitic subject, the possibility of traumatism causing such a condition is pointed out by Mott[1] who has met such cases following "a blow on the head which has set up an inflammation either in the bone or in the dura mater at a definite spot just as a blow on the shin may cause a periosteal node in a person the subject of syphilis."

In this case a clinical diagnosis had not been made and at necropsy the growth was not sufficiently distinctive to reveal its true nature. Microscopic examination of the meninges and brain showed no distinct abnormality except in the areas described, this ruled out dementia paretica, the excessive weight of the brain was likewise against this condition.

The microscopic findings conformed to those found in syphilitic pachymeningitis.

I am indebted to Dr. J. Allen Jackson of the Philadelphia Hospital for the Insane for the opportunity of studying this brain.

2005 Chestnut Street.

ABSTRACT OF DISCUSSION

DR. E. E. SOUTHARD, Cambridge, Mass.: How would you dianose the case under Kraepelin's classification?

DR. N. S. YAWGER, Philadelphia: I would regard it as a paranoid case in which syphilitic perimeningitis played a part.

GLYCOSURIA AMONG THE INSANE

CLARENCE EMERSON, PH.D., M.D.
Pathologist Hospital for Insane
LINCOLN, NEB.

This investigation into glycosuria of the insane was prompted by my interest in a case of mental aberration marked by melancholia and manifesting sufficient evidence of diabetes to raise the question of dependency of the psychic symptoms on that disease.

While our knowledge of the pathology of diabetes in the nervous system is incomplete it may be well to cite briefly the findings in a general way in order to note the impossibility of establishing a clear relation between glycosuria and mental disease on the basis of anatomic findings.

In the brain a variety of lesions in diverse locations have been associated with glycosuria. Spontaneous lesions as tumors, abscesses, hemorrhages and inflammatory thickenings, especially of the medulla and cerebellum near the place of Claude Bernard's puncture, but also in other parts of the brain, have been noted as causes of glycosuria. Tuberculosis of the hypophysis and the changes resulting in acromegaly are frequently associated with an excretion of sugar. In diabetes we have evidence of disturbed brain action, but we know so little of the cerebral pathology of diabetes and insanity that we cannot correlate these facts satisfactorily.

In the spinal cord, too, certain histologic pictures are undoubtedly dependent on the diabetic process and other lesions which seem to induce glycosuria. In some cases it is difficult to ascertain which is cause and which effect. Thus in diabetes changes occur in the posterior columns similar to those of tabes and there may be symptoms which raise a question of differential diagnosis, especially since it is known that glycosuria is not infrequent in tabes. Spinal cord tumor has been associated with glycosuria and thought to be its cause.

The peripheral nerves are usually the seat of inflammation during the disease, and the neuritic symptoms are common and numerous. Taylor has reported a tumor of the right vagus nerve accompanied by the presence of sugar in the urine. It has been stated in text-books that the cranial nerves are unaffected by the toxins of diabetes, but Merrill[1] has reported a case of nerve deafness due to this. Reference should be made to the theory of Pavy.[2] He has suggested that there is a cerebral influence on the vasomotor supply to the chylopoietic organs, that the nerve filaments from the sympathetic nervous system are connected with areas on the surface of the brain which function as cerebral vasomotor centers. The view which many are inclined to hold at present, that insanity is a functional disturbance of the brain due to toxemia, could fit in well with this theory to explain the frequent association of glycosuria and insanity.

It is the clinical rather than the pathologic findings which have raised the question of the significance of glycosuria in some forms of insanity. The toxins of diabetes undoubtedly have an action on nervous tissue. The neuritis occurring in diabetes manifests itself in numbness, anesthesia, paresthesia, hyperesthesia, cramps in the muscles, neuralgia, especially sciatica, falling nails, glossy fingers, perforating ulcer and gangrene of the toes. Diabetic paraplegia and "diabetic tabes," the complex of steppage gait, girdle sensation, lightning pains and lost reflexes are due to neuritis and cord changes. The loss of vibratory sensation described by Williamson[3] and fibrillary contractions (Pavy[2]) are neuritic. Anginal symptoms have been attributed to pneumogastric neuritis.

The effect of the diabetic toxemia on the cerebral centers is often observed. Mental disturbance of grave import is well known to accompany many cases of the disease. The usual form of aberration is a mild chronic depression with melancholia. Delusions of persecution, sin and ruin are not uncommon. There may be somnolence, confusion, disorientation, dulness of mind, irritability and restlessness. On the other hand, there are many and diverse disturbances of the cerebral function which are associated with a transient or permanent glycosuria. Numerous instances are recorded of the appearance of sugar in the urine following mental shock due to accident, operation, strain of competitive examination, etc. It is common knowledge that diabetes occurs with unusual frequency in families with a neurotic disposition. The frequent occurrence of glycosuria in the insane has been noted by Dawson,[4] Leeper,[5] Halberstadt and Arimoles[6] and others. Melancholia is the type of insanity in which glycosuria is most often found. It is interesting to speculate on the frequency with which a typical melancholic manifests glycosuria and a typical diabetic suffers profound melancholia.

Anatomic diseases of the central nervous system, as acromegaly and focal lesions in various parts of the brain and cord, have been associated with glycosuria.

REPORT OF CASE

Patient.—Mrs. M., housewife, aged 45, married, mother of four children, the youngest 17 years of age, menstruated regu larly, and no abnormalities were found by physical examination After some family trouble the patient worried unduly and manifested depression She was beset with fears regarding the safety of her son and daughter A stay of two weeks in a private sanatorium restored her to her usual frame of mind After her return she complained that she had been unable to get sufficient water at the retreat and to appease her thirst she had drunk from the bath tub Six months later without evident cause there was a second attack of mental disturbance in an aggravated form She was sleepless, cried and prayed continually, and feared that death was soon to befall her son and daughter She reproached herself for giving so meagerly to the church and the poor and was greatly concerned about the restraint applied to some patients in the violent ward Violence was manifested for a day or so when it was necessary to watch her closely to prevent her from choking or otherwise injuring other patients A delusion was developed in regard to her relationship to another inmate

Examination and Treatment—During this time there was no particular evidence of thirst, but urinary examination disclosed a high percentage of sugar There were no neuritic or infectious manifestations of the disease Constipation was marked and obstinate to treatment When the patient was placed on antidiabetic diet, first soup and then carbohydrate free, sugar ceased to appear in the urine She became less melancholic ceased crying and praying, gave up her delusions and later her fears, so that after a period of three weeks there was no evident mental disturbance The relatives insisted on a return to her home against advice A promise to employ a nurse and adhere to strict diabetic management under the guidance of a physician was not fulfilled In four days she was returned because of depression, sleeplessness and a partial return of delusions After two weeks delusions were again lacking, but she continued to worry and was in a state of melancholy when she eloped assisted by relatives After an absence of about a month she was again returned Her mental condition at that time was practically the same as now though her physical condition is somewhat improved At present she is very depressed, cries a great deal and is possessed of her delusions though she does not manifest them unless questioned Sugar appears in the urine occasionally, but is not constant with the general ward diet None of the urinary examinations disclosed diacetic acid and the ammonia output was not increased.

At present I believe that most psychopathists would pronounce the patient a melancholic When she was first brought to the hospital the large percentage of glycosuria high specific gravity and polyuria were certainly suggestive of diabetes The amelioration under treatment strengthened this belief but the subsequent return of the mental condition without glycosuria, the absence of symptoms of diabetes and polyuria favor the diagnosis of melancholia with associated sugar excretion This experience serves to emphasize the close relationship symptomatically between this form of insanity and diabetic psychosis and illustrates the need of time and repeated urinary examination in the differentiation of the two in certain cases To determine something of the significance of the sugar reaction in the urine of the insane the records of 650 urinalyses made on admission of patients to the Nebraska Hospital for the Insane have been examined A total of 4 28 per cent gave a positive sugar test The table illustrates the division of these cases among the 650 patients according to the type of insanity together with the percentage of cases showing glycosuria in each variety of mental disease In involutional melancholia 22 per cent had glycosuria —a much higher percentage than is found in any other variety Organic dementia comes next with 12 per cent This tends to corroborate previous observations that various lesions of the brain are frequently associated with glycosuria There are more cases of glycosuria among the dementia praecox class than among the manic-depressives in this series

Quite frequently a patient will pass sugar in his urine during the first few days after admission and not again subsequently Twenty-four-hour specimens were not always taken in earlier records The quantity of urine was not increased in four cases of temporary glycosuria which I examined

TABLE COMPARING RELATIVE FREQUENCY OF GLYCOSURIA IN DIFFERENT TYPES OF INSANITY

Type of Insanity	Number of Cases	Per cent of Cases	Number with Sugar	Per cent with Sugar
Dementia praecox	253	38 70+	7	2 66+
Manic-depressive insanity	54	8 20+	0	1 02+
Dementia paralytica	64	9 79+	2	34+
Involutional melancholia	9	1 38+	2	22 00+
Senile dementia	56	8 56	2	36+
Not insane	18	2 75	1	5 00+
Organic dementia	8	1 22+	1	12 00+
Epileptic insanity	25	3 82+	1	4 00+
Unclassified	32	4 89+	1	3 1
Intoxication psychoses	60	9 18+	2	3 2
Paranoid states	28	4 28+		
Defective development	32	4 89+		
Huntington s chorea	1	15+		
Total	650		28	4 28±

The association of permanency of glycosuria with high specific gravity was noted in thirty-two patients A high percentage of cases with glycosuria among these insane had a low specific gravity Those with permanent glycosuria for the most part had a specific gravity above 1 030 Occasionally a transient glycosuric urine had a high specific gravity

An examination of epileptics with reference to glycosuria has not been completed I may mention that of six taken indiscriminately in which daily urine examination was made for twenty days, five showed a sugar reaction one or more times In none of these did it occur persistently

A brief epitome of facts gleaned in this study may be of service The sugar reaction is frequently obtained in the urine of the insane especially of melancholics and those with organic brain lesions The condition is usually a temporary one occurring at more or less frequent intervals or only during the first few days after admission The case reported illustrates the need of repeated tests to exclude the presence of a diabetic process The permanency of the glycosuria, specific gravity, polyuria, thirst, neuritides and ammonia output should be considered in differential diagnosis If the sugar is abundant and present over a considerable period of time antidiabetic management should be instituted The importance of the sugar test must not be underestimated in view of the resemblance symptomatically of the diabetic psychosis and melancholia

The discussion of the cause of the frequent appearance of sugar in the urine of the insane can be but speculation Certain factors of instigation are recognized The mental agitation and distress experienced by many who have insight into their condition explains the occurrence of glycosuria on admission The gluttony especially common among epileptics is responsible in all probability for frequent temporary appearance of sugar

TWO CASES OF ACUTE PRIMARY CHOLECYSTITIS PRESENTING UNUSUAL FEATURES

N W JONES, M D
PORTLAND, ORE

The unusual clinical picture of the following two cases of gall-bladder disease prompts me to report them as examples of acute primary cholecystitis

CASE 1 —*History* —The patient, a large heavily built Italian of intemperate habits, aged 47, was suddenly seized at 3 p m, Dec 21, 1911, while attending to business, with excruciatingly severe cramping pain in the upper abdomen He was prostrated with it and was soon bathed in cold perspiration There was no chill or subsequent fever My father attended the patient at his home shortly afterward, where this condition was noted Morphin sulphate, one fourth gram, and atropin sulphate, 1/150 grain, were given hypodermatically At 9 p m the pain was still present in paroxysms and the morphin and atropin were repeated At this time some delirium was noticed At 6 a m the following morning the patient was still thrashing about the bed in pain and more marked delirium The morphin and atropin were again repeated, making three-fourths grain of morphin sulphate that was given in fourteen hours At 11 a m I examined the patient, who was lying on his back in semicoma, from which he could with difficulty be aroused His pupils were small but reacted to light Breathing was stertorous and the breath was not particularly foul Deep reflexes were present and not exaggerated There were no local physical findings The urine showed no change The patient sank rapidly into deep coma and died at 1 p m, twenty two hours from the time of onset

The patient's previous history, obtained from his wife, was to the effect that he had suffered a few attacks of pain in the upper abdomen during the previous seven years There was no history of typhoid The case had been considered one of gall stone colic, until the approaching coma pointed to morphin poisoning, although it was not the clinical picture of such

Necropsy —This revealed an enlarged, tightly engorged, blackish gall bladder, projecting free from the under surface of the liver, without the presence of local peritonitis On firm pressure the contents of the gall bladder could be slowly expressed into the intestine When the gall bladder was opened, a thick black bile escaped, carrying with it six small stones In four places the wall appeared ready to break through, but nowhere had a gross perforation taken place The remainder of the body, except the brain, which was not examined, showed no gross lesions No cultures were taken

CASE 2 —*History* —Mr G, a large muscular man, aged 54, had suffered off and on for about two years with periods of irregular stomach distress attacks of pain, rather frequent vomiting and on several occasions the vomiting of considerable quantities of blood The patient was imbued with that peculiar spirit of Scotch stoicism which prevented him from speaking of his own ailments and in consequence but little information could be obtained from his family or friends He had been a hard, steady drinker for many years He was subject to small attacks of fever and headache, but gave no history of having had typhoid

Examination —Dr A D Walker saw the patient first on Friday, March 2, 1912, at his home in the country He was then in bed with a fever of 101 F and was mildly delirious, but could be aroused easily He was seemingly in some pain There were no local physical findings of gall bladder disease, the abdomen, however, was somewhat diffusely tender to pressure, especially along the line of the colon On Sunday evening the patient became maniacal and it required several men to hold him in bed Dr Walker saw him on Monday morning in a state of collapse, quite unconscious, at times mildly maniacal, and with a little fever From Friday until he became unconscious on Sunday he had not complained of great pain Monday evening I examined him with Dr Walker at St Vincent's Hospital He was unconscious but still restless His pupils were of moderate size and reacted to light The deep reflexes were present but sluggish The skin was pale and bathed in cold perspiration There was no jaundice. I thought, however, that a definite degree of rigidity existed over the gall bladder region

This fact, together with the rapidly progressing toxemia and coma, the previous history of attacks of abdominal pain and the experience gained from my previous case, which resembled this one in many respects, made me urge the possibility of an acute gangrenous cholecystitis and advise immediate exploration of the upper abdomen Dr Walker called in consultation a surgical confrère who could not see a surgical aspect to the case Death occurred early Tuesday morning, accompanied by a diffuse edema of the lungs

Necropsy —This was performed four hours after death and disclosed an enlarged engorged, black gall bladder filled with black moderately thick bile without any stones The bile by considerable pressure could be slowly expressed into the intestine The wall was irregularly mottled with gangrenous areas, but there was no gross perforation and no definite peritonitis about the bladder The peritoneal cavity was quite intact. The stomach mucosa was dull gray, covered with abundant thick mucus and possessed several areas of old and recent blood extravasations The lungs on the cut surface were wet with frothy fluid and had no areas of consolidation in them

Cultures made on plain agar slants from the contents of the gall bladder by Dr Ben Wade remained sterile

In a fairly extended search through the literature no instances of acute gangrenous cholecystitis in which local symptoms were masked by an active delirium and coma were found Mellerio[1] reports four cases of acute infectious cholecystitis without stones from the private clinic of Jordan of Heidelburg, in one of which an active delirium occurred later in its course There were present, however, severe sudden pains in the right upper abdomen, early chills and jaundice

The bacterial cause of the acute inflammation in the absence of stones has been undiscovered in the majority of instances Adolf,[2] at the Frankfort clinic, reports a case in which the colon bacillus was found in the discharge from the gall-bladder The colon bacillus and the *Staphylococcus aureus* were recovered from the contents of the gall-bladder of the fourth patient of Mellerio Riedel[3] found streptococci in the bile from the gall-bladder from one patient Six other patients had sterile bile in the presence of acute gangrene Ross[4] reports five cases of acute gangrene of the gall-bladder without determining a specific infection in any of them Keyenburg[5] reports three cases of his own of acute cholecystitis without stone and five more from the literature in which the infection is not stated to have been determined Schwarz[6] failed to discover the infection in one case

It is quite evident that the clinical picture of both of my cases was dominated by the intense general toxemia arising from the gall-bladder What determined this intoxication or the type of infection producing it remained hidden There was nothing new determined in regard to the pathology of the disease The entire absence of secondary peritonitis, however, was noteworthy

In the first case the presence of an old cholecystitis was evidenced by the few stones found in the bladder Whether these in themselves exerted any influence in the production of the severe pain is problematical because the cystic and common ducts were patent to sufficient pressure and did not contain any stones

6 Schwarz Wilhelm München med Wchnschr 1908 lv, 2766

It seems to me that the acute disease of the gall-bladder in the second patient need not necessarily be looked on as secondary to a preexisting chronic cholecystitis, for the reason that there were no stones present and that the severe hemorrhagic gastritis was quite capable of explaining the patient's ill health during the preceding two years I am quite aware, too, that repeated stomach bleedings do occur because of the probable action of toxins, arising in an infected gall-bladder, on the mucous membrane, but in this instance, a true chronic gastritis existed and also the etiologic factor of chronic alcoholism It may be possible that the influence of the latter factor, namely, chronic alcoholism, in both cases, determined in a measure the susceptibility of the patient to absorb the toxins formed

There is present a certain similarity between this type of case and an acutely fulminating infection in any part of the abdominal cavity The extreme collapse and early delirium is at times seen in appendiceal disease or in acute pancreatitis It would seem from these cases that the oncoming of an early delirium in association with any acute abdominal condition should be picked out as a tangible and important indication for immediate exploration whether localizing signs were present or not, for surely the body which shows itself so susceptible to intoxication will not respond to means of elimination until after the focus of infection is removed.

UNILATERAL OPTIC ATROPHY AND CONTRALATERAL HEMIPLEGIA CONSEQUENT ON OCCLUSION OF THE CEREBRAL VESSELS

WILLIAMS B CADWALADER, M.D
Instructor of Neurology and Neuropathology at the University of Pennsylvania Clinical Assistant to the Philadelphia Orthopedic Hospital and Infirmary for Nervous Diseases
PHILADELPHIA

Occlusion of one middle cerebral artery producing hemiplegia on the opposite side of the body is an everyday occurrence, furthermore, optic atrophy as a result of obliteration of the retinal vessels on the same side is well known, but the combination of unilateral optic atrophy and contralateral hemiplegia is seldom encountered and might be very confusing

Cases of this kind have been described by Elschnig,[1] Gowers,[2] Hughlings Jackson,[3] Siegrist,[4] Williamson,[5] Batten and Guthrie,[6] Guthrie and Mayou,[7] Oppenheim,[8] von Monokow[9] and Starr[10] With the exception of a brief reference in Starr's text-book, I have not been able to find any description of this symptom-complex in American literature, therefore it seemed important to record the following cases

The first case was seen in the service of Dr John K Mitchell at the Orthopedic Hospital and Infirmary for Nervous Diseases, and the second at the University Hospital in the service of Dr Charles K Mills To them I wish to express my thanks for permission to make this report.

Case 1 —*History* —M M, a man aged 35, was admitted to the Orthopedic Hospital and Infirmary for Nervous Diseases, in the service of Dr J K Mitchell, Jan 8, 1911 Syphilis and alcohol were denied About six weeks previous to admission the patient had had an acute illness, said to have been influenza During that time, while confined to bed, he suddenly developed a partial loss of consciousness, lasting a few minutes, with weakness of the right side of the body, including the face, arm and leg, there was also dimness of vision in the left eye and aphasia Previous to this attack the vision had been normal

Examination —There was nearly complete motor aphasia, but no evidence of sensory aphasia, marked weakness of the right side of the face, cerebral in type, with spastic paralysis of the right arm and leg The tendon reflexes were increased and there was ankle clonus and Babinski sign Vision of the right eye was normal, but the left eye was totally blind Sensation was impaired for touch throughout the paralyzed side of the body The other cranial nerves were normal The heart was normal in size and regular, the sounds though fairly good were lacking in muscular tone Dr Langdon, who repeatedly made examinations of the eyes, reported that the right eye, except for slight grayness of the disk, was normal This was not the grayness of true atrophy In the left eye the arteries were cut down to mere threads, indeed, the inferior temporal branch appeared like a fibrous cord This, with the macular changes, can readily be caused by occlusion of the central artery The Wassermann reaction was negative

Except for blindness and optic atrophy on the same side as the vascular lesion, this case differs in no way from the most commonplace embolic apoplexy with resulting hemiplegia The character of the onset and course of the apoplectic attack itself, as well as the character of the paralysis, were not unusual, the patient, however, immediately after having recovered from the shock of the initial apoplexy complained of dimness of vision on one side, which rapidly progressed to total blindness At first an explanation was difficult, but an ophthalmoscopic examination revealed optic atrophy, with the characteristic empty, thread-like appearance of the retinal vessels

The cases of Batten and Guthrie,[6] of Jackson[3] and of Gowers,[2] which were studied at necropsy, have proved that an embolic mass can be carried through the internal carotid artery into the middle cerebral vessel, producing apoplexy and hemiplegia, at the same time a portion can be swept into the ophthalmic artery, as it branches from the internal carotid, or it may even be lodged in the central artery of the retina, and thus produce sudden blindness and atrophy

In most instances blindness develops suddenly, though in one of the cases described by Batten and Guthrie optic atrophy was probably not completed for nearly three months after the initial apoplexy, a portion of the occluding mass in the internal carotid vessel may have been subsequently swept into the right ophthalmic artery Singer[11] found, while producing embolic apoplexy experimentally on guinea-pigs, that occlusion of one retinal artery and subsequent optic atrophy almost invariably occurred Undoubtedly there must be some peculiar arrangement of the central vessels in guinea-pigs, explaining the frequency of this occurrence

It is not difficult to understand how optic atrophy and hemiplegia can be produced, if we remember the manner in which the terminal branches of the internal carotid vessels are distributed It divides into the middle cerebral, which supplies the basal ganglia, internal capsule, etc , close to the point where the middle cerebral is given off the ophthalmic is derived, which divides into two main groups, the orbital and ocular groups The second group consists of the muscular, anterior ciliary, long and short ciliary and the central artery of the retina, the latter perhaps the smallest of all and possibly more easily occluded than the other branches

[11] Singer Ztschr f. Heilk., 1897 xviii 105

Naturally, the position of the occlusion in the ophthalmic artery or in one of its branches has an important bearing on the resulting signs Unilaterality of visual disturbances is in itself an important indication of a localized vascular lesion In syphilis bilateral and symmetrical involvement would generally occur, or, at least, if one eye was affected, the other would show some evidence of disease even though relatively insignificant Williamson has described unilateral retinal changes occurring with cerebral hemorrhage, embolism and thrombosis, in thirteen cases In eleven the diagnosis was verified by post-mortem examination, and in two the diagnosis seemed correct clinically In four cases of hemorrhage and one of embolism a large retinal hemorrhage occurred on the same side as the cerebral lesion, while the retina of the other eye was practically normal In one case the retinal vessels were markedly dilated and tortuous on the side of the lesion

Oppenheim,[8] in his *text-book*, speaks of an instance in which there was unilateral optic atrophy with contralateral hemiplegia accompanied by considerable headache and tenderness on the side of the atrophy He believed that it was caused by a tumor, but the necropsy revealed cerebral softening Indeed, tumor might easily be confused, particularly when it is situated in or near the frontal lobe, as in the cases described by Gowers, Horsley and Kennedy

For diagnostic purposes the appearance of optic atrophy when caused by vascular occlusion is more or less significant Herbert Parsons[12] says

> A large mass of evidence has already accumulated to show that of all parts of the ocular circulation the part in the immediate vicinity of the lamina cribrosa is the most liable to be affected by vascular disease in any form *This undoubtedly* is true in regard to obstruction of the central artery whether it be due to embolus, endarteritis or endarteritis combined with thrombosis

Parsons divides the appearance of the various stages of atrophy as follows at first, the arteries are thread-like from more or less sudden cutting off of the bloodstream, later, there is some refilling from the establishment of a collateral circulation, and finally, the arteries are thread-like and sclerosed, associated with optic atrophy

Unilateral optic atrophy may occur as the result of localized endarteritis or a combination of arteritis with thrombosis, without hemiplegia, but apoplexy and hemiplegia can develop subsequently, and then examination will show unilateral optic atrophy with contralateral hemiplegia, nevertheless an accurate history of the time of onset of blindness and a careful ophthalmoscopic examination should make the diagnosis possible This condition is well illustrated by the following case

Case 2 —*History* —P R, a man aged 52, was admitted to the University Hospital, in the service of Dr Mills, Nov 15, 1911 Family history was negative Patient denied syphilitic infection and alcohol During 1909 and 1910 he had complained of dimness of vision on the left side. In February, 1910, he had a series of general convulsions Three days later he suddenly lost consciousness After regaining consciousness he was unable to speak and was paralyzed on the right side of the body

Examination —There was typical right hemiplegia with spasticity, increased tendon reflexes, ankle-clonus and Babinski sign and nearly complete motor aphasia Sensation was not affected On the left side there was complete blindness Ophthalmoscopic examination showed optic atrophy with great diminution in the size of the retinal vessels, which were sclerotic The retinal vessels of the right eye were moderately sclerotic, but vision was not much impaired

CHICAGO

By scoliosis we mean a deformity characterized by lateral deviation of the spinal column, associated with a rotation of the bodies of the vertebrae around a vertical axis *In this* position of rotation the bodies face toward the resulting convexity, while the spines of the vertebrae point in the opposite direction, a slight deviation of the spines does not always indicate an equally slight degree of aberration of the vertebral bodies

Further, as a result of the rotation, the transverse processes on the side of the convexity are directed backward, and carry with them, in the dorsal region, the ribs, whose angles become more or less prominent according to the degree of deformity

In scoliosis of slight degree the angulation itself may not be marked, instead, a costal bulging or boss is formed, which becomes more noticeable when compared with the flattened area of the opposite side of the chest Also, on the side of the spinal convexity the scapula is pushed away from the spinal column and the shoulder raised, while on the concave side the shoulder drops and the scapula approaches the vertebral column

Often the deformity is so slight as to be overlooked, particularly when the patient attempts to sit erect, hence, it is of much importance, in beginning the inspection of a patient, to permit him to sit at ease, or, even to slouch, if he will

For our purpose it is necessary to consider the matter of compensation in scoliosis, in moderate cases, even, of scoliosis, a compensatory convexity is produced in the vertebral column In the thoracic bony structure, also, compensation occurs, as follows

Diagonally across the chest from the posterior costal angulation or bulging above mentioned, is found a second, less emphasized angulation or bulging, while a flattened area is observed on the opposite side of the chest anteriorly, i e, on the same side of the chest as the posterior bulging alluded to For example, given a dextroconvex scoliosis in the upper dorsal region the greatest angulation or bulging of the thoracic wall will be to the right of the vertebral convexity, while the compensatory angulation will be found to the left of the sternum just below the clavicle The flattened areas will lie to the left, behind, and to the right in front Again examining the back, we should logically expect to find further increased angulation of the ribs on the side of the lower vertebral convexity (the left side), this is the case, in lesser degree, however, inasmuch as the floating ribs, not being anchored are not so much angulated by the rotation of the vertebrae

In order to detect these sl [illegible] al de [illegible] the patient should sit in a [illegible] and [illegible] he position most comfortable [illegible] ev [illegible] d slouchy it may be The admonition of the physician to sit erect tends to defeat the end aimed at It may be necessary to allow the patient to sit quietly for some time before he relaxes sufficiently to show the deformity

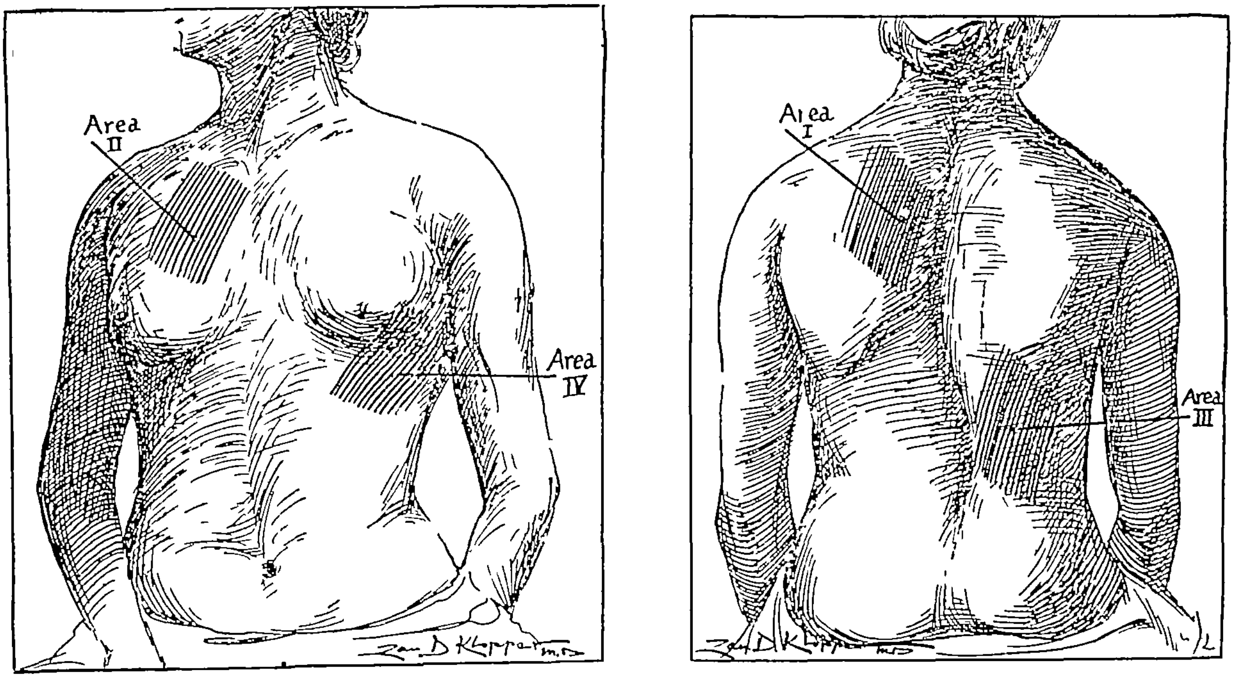
---

[12] Parsons Herbert The Pathology of the Eye pp 1262 1265

It must be remembered that patients may sometimes confuse percussion findings by muscle play, this point is especially of importance when the deformity is slight and physical signs not pronounced

Note is now made of the relative height of the shoulders, of the position of the scapulae and their distance from the spinal column at their inferior angles, this difference may range from 1 cm to 5 cm The presence of a one-sided supraclavicular fossa should receive consideration, while, in women, the difference in the position of the breasts should attract attention

As the patient continues to relax, the head is often tilted to one side — this in furtherance of compensation As the physician stands behind the patient and looks downward on the latter, the increased prominence of the one side in front is readily seen, unless the deformity be slight.



Areas of high pitched percussion notes in dextroconvex scoliosis

Passing now to percussion we find the distinctive changes in physical signs which especially characterize the scoliotic chest, provided, however, that there is no disease of the lungs which has affected their integrity

Let us percuss first the upper portion of the chest, behind, on the side of the vertebral convexity, we elicit a shorter and higher-pitched note than on the opposite or flattened side that is, on the side of the spinal concavity, where we often find marked resonance

Percussing the lower part of the chest, now, we elicit another high-pitched note over the area on the side of the lower vertebral convexity on the side of the lower vertebral concavity we find another area of resonance

Anteriorly we percuss the area of compensatory angulation and again obtain a short, high-pitched note as compared with the sound elicited from the flattened chest wall on the opposite side A fourth, more or less inconstant, high-pitched area is found diagonally across the front of the chest from the infraclavicular area just mentioned

In intensity the high-pitched areas rank as follows

First, posteriorly, opposite superior vertebral convexity

Second, anteriorly, over the infraclavicular region

Third, posteriorly, below, opposite lower vertebral convexity

Fourth (when present), anteriorly, below, diagonally across from superior infraclavicular area

To exemplify the problem in sound-production here adduced, I have prepared two bars of iron, both of the same length The straight bar we may use to represent the flattened and resonant areas, while the bent bar may be taken for the angulation areas Percussion produces a resonant note in the straight bar and a short, high-pitched tone in the arch

Sahli says

> Increased convexities of the thorax produce dulness which can be best noted in scoliotics and kyphotics This dulness occurs because of the increased rigidity of the more convex rib which vibrates less and allows percussion force to be lost A flattened rib permits of increased vibration under percussion, hence, a somewhat hyperresonant note over the flattened tract

Bachmann (1899), Bouvier, West, Mosse, Kaminer and Zade, as well as other authors, have called attention to the phenomena under discussion, but the subject has been most thoroughly treated and formulated by Neumann.[1]

Given a case of slight scoliosis minus actual lung disease, the high-pitched areas here described are quite constant Where, however, thickening of the pleura has occurred, the percussion note may be found over other areas than those presented in our scheme Differentiation between the signs accompanying empyema or effusion and the schematic signs found in scoliosis should present no difficulties

Early tuberculous consolidation usually presents an area of dulness in front as well as behind on the same side, this is not true of the scoliotic phenomena Further, in advanced tuberculosis, even when, as often, it is accompanied by marked scoliosis, the areas of high pitch are practically never schematically demonstrable The upper areas of high pitch in scoliosis may be, and often are, mistaken for apical tuberculous catarrh, but, in the absence of corroborative physical evidence, front and back, on the same side, such a diagnosis is at least, doubtful — especially in the absence of other data

---

[1] Neumann, Wilhelm Beitr z Klin d Tuberk., xviii, No 3

Neumann has called attention to the limited downward excursion of the lung on the side opposite the upper vertebral convexity Not only is the motion usually limited, but also, in some cases, as I have observed, it is entirely eliminated

Diagnostic error in early tuberculosis is often on the side of omission, unless we remember that other conditions may influence variations in pitch, the error may be readily transformed into one of commission Although this error is not fraught with such fatal results as the former, it is capable of producing much distress to those involved

Two cases which have come to me within the last year demonstrate this point One, in a lad of 15, was diagnosed as incipient tuberculosis, and change of climate was advised Examination showed a mitral regurgitation, marked scoliosis, schematic, high-pitched areas, no fever, no tubercle bacilli and no albumin in sputum and no reaction to 5 mg T O The patient has done well since, without treatment He consulted his physician on account of a "cold"

The second patient, a woman, 40 years of age, came with a diagnosis of moderately advanced tuberculosis, she had no fever, absolutely no sputum, a pulse 68 to 72, no lung signs, she had marked scoliosis with easily demonstrable areas of high pitch T O, in doses of 5 and 10 mg respectively, failed to produce reaction, either general or local

I have found these high-pitch areas in many other scoliotics who have presented no other discoverable signs which might be considered as being indicative of tuberculosis — and who are, clinically, well These percussion changes in scoliosis should be borne in mind when tuberculosis is merely suspected but demonstration by classical signs is not possible, they should not be held to be conclusive, nor should their presence militate in any way against a careful search for other pathologic phenomena

2744 Pine Grove Avenue

PLEA FOR EARLY SURGICAL INTERVENTION IN ALL UMBILICAL HERNIAS [*]

J W KENNEDY, M D
PHILADELPHIA

Some time ago I read a paper entitled "Urgent Conditions in Abdominal Surgery," in which I strongly advised closure of all umbilical hernias before any strangulation takes place For the past six months I have been asked so often to operate for strangulated umbilical hernia that I again call attention to this urgent condition

Umbilical hernia is a common condition In many particulars this hernia is unfavorable for a prolonged operation, and therefore I make a plea for more prophylactic surgery The patient is as a rule aged between 45 and 60 years, and is a fleshy person with poor resisting powers The pathology of the umbilical hernia much complicates the condition That typically honeycombed dissection of the viscera between the fascia and the skin, which is so characteristic of umbilical hernia, makes the operation long and tedious In this class of cases the strangulation is often incipient in onset, therefore the patient is profoundly or fatally toxic ere any marked symptoms of strangulation reveal themselves

On account of the gradual onset, extensive involvement of the viscera has taken place before recognition of a serious condition, necessitating major resection or prolonged surgery Rarely do I see a patient before fecal vomiting has taken place, and at this stage it is too late to save many of these patients A partial strangulation of the bowel, which may have taken place for weeks, is the probable cause of the fatal toxemia Absorption of toxins has been taking place from the mucous membrane of the partially obstructed bowel, and the bowel early becomes infected throughout its structure

The surgical difficulties encountered are ominous The strangulated structures have been external so long to the true abdominal cavity and have become hypertrophied to such an extent that it is impossible to return the viscera without unduly increasing abdominal tension and thus profoundly or fatally shocking the patient Again, the viscera have been external so long that when returned to the abdominal cavity they act as a foreign body with a resultant fatality I have seen the mesentery of the small bowel so elongated from its false position that the intestine could be drawn over a foot above the abdominal incision The mesentery to the particular loop of bowel which has been external to the abdominal cavity is often so definitely elongated that I call it "a peninsular of the mesentery" This will require extensive resection of the mesentery and bowel if an attempt is made to close the hernia

If operation is delayed in this class of hernia until operation becomes a necessity, only a small percentage of patients can be saved In these mammoth hernias the mortality is high even when there is slight or no strangulation I am positive that the mortality in abdominal surgery is too high all over the world when compared with our real surgical privileges in this age, and that it is our own professional fault Our mortality in abdominal surgery should not be over 1 per cent

I cannot agree with the physician who, after giving advice for surgical intervention in some particular condition, continues to treat that patient along medical lines with the idea that he has unburdened his conscience by simply advising surgical intervention If he continues to treat the patient along lines which he does not approve, he is an accomplice in a professional crime His attentions should end when his advice is not taken If we all did this, it is easy to see how much earlier we would meet these fatal conditions Indeed, if you have washed your hands and properly tied the vessels with reliable materials and review your list of deaths, the simple phrase "too late" should span the mortality

It is always with the greatest professional apprehension that I think of the untimely death of Joseph Price, that greatest advocate for early surgical intervention The present physiologic era in abdominal surgery will bury many patients without even a chance of surgical privileges I grow bitter under [illegible] It does not make much difference wl [illegible] ne of treatment is in these large, [illegible] The bowel [illegible] be resected, the [illegible] ort circu [illegible] bowel opened and drained without resection and the abdominal cavity drained or closed, yet the mortality is appalling The treatment must practically be prophylactic By this I mean that it must be given not only before there is any strangulation of viscera, but before the hernia becomes of extensive proportions

A REPORT OF SOME NEW CHEMICAL ANALYSES OF URINARY CALCULI

WITH INDICATIONS FOR TREATMENT *

MAX KAHN, M D, Ph.D
NEW YORK
AND
JACOB ROSENBLOOM, M D, Ph D
PITTSBURGH, PA

We present in this paper quantitative chemical analyses of twenty-five renal calculi and of two cystic calculi, showing that the true renal calculi were composed almost entirely of calcium salts, while the cystic calculi were composed almost entirely of uric acid Our series of calculi were all obtained from patients who lived in this country and our results can be compared with those obtained by several workers in England who obtained results similar to our own

Rowlands[1] in his investigations of twenty-two stones came to the following conclusions that renal calculi were composed almost entirely of calcium oxalate, that uric acid is usually absent and if present it is so only in very small traces, that phosphates are commonly present Mackarell, Moore and Thomas,[2] in a series of twenty-four analyses, corroborated the results of Rowlands

We have analyzed quantitatively sixteen calculi from patients of various hospitals of New York City Table 1 gives a report of the percentage composition of the various components of the stones of this series[3]

TABLE 1—PERCENTAGE COMPOSITION OF SIXTEEN RENAL CALCULI

No	Weight, gm	Moisture Per Cent.	Calcium Oxalate Per Cent	Uric Acid Per Cent	Phosphorus Pentoxid Per Cent
1	12 0446	0 11	37 4	3 50	51 50
2	0 5114	4 1	94 7	2 1	5 3
3	13 982	2 1	29 5	7 46	56 2
4	0 6009	1 08	68 4	7 3	7 8
5	14 998	0 23	94 1	0 2	6 1
6	2 4505	3 2	72 3	23 6	4 3
7	6 175	1 8	90 5	0 01	0 5
8	4 0349	0 04	98 7	1 01	6 4
9	5 7725	0 02	94 2	1 8	4 6
10	2 8004	0 15	81 6	9 3	9 5
11	15 9125	0 4	73 8	7 5	20 1
12	0 9329	0 43	80 4	10 8	6 5
13	0 1612	0 05	91 3	2 46	5 23
14	1 6064	0 099	70 2	12 1	16 9
15	12 8478	0 3	90 37	3 4	6 21
16	9 7621	3 1	91 3	7 2	2 1

The following conclusions may be drawn from these analyses 1 The large majority of renal stones are composed of oxalate of lime 2 Uric acid and the urates are found in all renal concretions, but it is rare to find a renal calculus that is mainly composed of the urates 3 The shape, color consistency, etc, of a stone do not form a criterion of its chemical composition

Recently a series of eleven stones was analyzed by one of us[4] Very nearly corresponding results were obtained Nine of the stones were renal and two of them were cystic The following table records the amounts of the various constituents found

TABLE 2—PERCENTAGE COMPOSITION OF NINE RENAL CALCULI

Received From	No	Moisture Per Cent	Calcium Oxalate, Per Cent	Uric Acid Per Cent	Calcium Phosphate Per Cent
Dr MacCallum New York	17	3 0	68 1	9 11	1 5
Dr MacCallum New York	18	4 1	21 5	6 3	70 8
Dr H Fischer New York	19	2 1	81 1	1 9	11 6
Dr Rosenbloom New York.	20	4 3	43 2	0 6	45 4
Dr Kammerer New York	21	4 0	30 1	0 0	64 2
Dr Rosenbloom Pittsburgh	22	10 3	30 5	0 0	50 6
Dr Rosenbloom Pittsburgh	23	8 2	0 0	0 0	0 0
Dr Sembken New York	24	3 1	90 2	1 8	4 3
Dr Rehling New York	25	5 2	70 8	1 2	20 1

Nitrogenous substances were present in stones 16, 17 and 18, a total nitrogen determination of these stones gave 1 3 per cent, 4 6 per cent and 3 3 per cent respectively Nevertheless, by the method used for the direct uric acid determination, negative results for urates were obtained

TABLE 3—PERCENTAGE COMPOSITION OF TWO CYSTIC CALCULI

Received From	No	Moisture Per Cent	Calcium Oxalate, Per Cent	Uric Acid, Per Cent.	Phosphorus Pentoxid Per Cent
Dr MacCallum	26	7 1	0 0	96 8	0 0
Dr H Fischer	27	6 2	trace	98 0	0 0

We have also examined three gouty tophi and in none of them could we find any uric acid This would tend to show some relation in the metabolic disturbances of gout and renal lithiasis Certain principles for the treatment of both of these conditions will now be considered

SUGGESTIONS FOR THE TREATMENT OF RENAL LITHIASIS

It is quite conventional to recommend alkaline solutions to patients afflicted with stone disease The salts of lithium have enjoyed a great reputation for their supposed wonderful solvent action on renal concretions Whyte and Deften considered alkaline solutions as true solvents for renal calculi Hoffman, Springsfield, Alston, Leger and others recommended alkaline treatment for nephrolithiasis Morgagni suffered from gravel, and his remedy was half a dram of the potassium carbonate during the day "The acid of his urine soon became saturated, the pains in his loins diminished, his urine became less loaded and potash was at length found in that fluid in excess" From Pepys' diary we extract the following procedure for the treatment of stones "And at this season of the year we go to Tunbridge Wells to drink the waters and to get rid of our gravel, to which end we are aided by taking small doses of turpentine" Nowadays it is quite the custom for those who can afford it to go to various bathing and water-drinking resorts, where they ingest alkaline water for the treatment of gout and gravel We believe it quite absurd to imagine that the amount of alkaline metal that is excreted by the kidneys in the urine is of sufficient concentration to cause any but a theoretical solution of the stony concretion

The fact that, as has been shown the majority of renal calculi are composed of insoluble salts of calcium and

[1] Rowlands Biochem Jour 1908 iii 346

[2] Mackarell Moore and Thomas Biochem Jour 1911 v 161

[3] These analyses were conducted in the Biological Chemistry Laboratory at the College of Physicians and Surgeons Columbia University New York City by Dr Kahn at the suggestion and under the direction of Dr Rosenbloom

[4] These analyses were carried out by Dr Rosenbloom at the Chemical Laboratory of the German Hospital

not of uric acid or urates, forcibly brings to our attention the necessity of changing our therapeutic ends in regard to the treatment of renal calculi The therapeutic measures for the treatment of insoluble calcium salt concretions are completely different from those employed for uric acid The usual antacid treatment is just the opposite of what is indicated because while uric acid and its acid salts are soluble in alkaline mediums and insoluble in acid, the exact opposite holds for calcium oxalate and calcium phosphate, which are deposited in alkali mediums and dissolved by acids

We therefore conclude that all calculi obtained by operation or otherwise should be subjected to chemical analysis and that if they are found to be composed of calcium salts, no antacid treatment should be advised, as this would lead to a more rapid growth or to increased chance of growth and instead of the non-acid treatment, it would be most advisable to try a course of acid treatment

COCCIDIOIDAL GRANULOMA

REPORT OF THE NINETEENTH CASE IN CALIFORNIA

F H BOWLES, M D
OAKLAND, CAL.

Up to this time eighteen cases of coccidioidal granuloma have been reported and traced to California, the seventeenth and eighteenth being reported by Brown[1] of San Francisco, with review of the literature The first case in California was discovered by Rixford[2] of San Francisco, and later described in conjunction with Gilchrist[3] of the Johns Hopkins Hospital Medical School Afterward Ophuls[4] of San Francisco described the fungus with certain morphology and characteristics, giving the name of *Oidium coccidioides,* with report of thirteen cases, differentiating the fungus from the closely related *Blastomyces coccidioides* of which much has been written, the latest article being by Hektoen[5] of Chicago

The mold appears to be of animal origin, though not proved with occasional infection in man Most infected persons came from the lower half of the San Joaquin valley, and were men employed in railway construction or in caring for animals The duration of the disease, so far reported, is from six months to nine years Most of the patients gave histories of bone lesions, some having accompanying lesions like hypertrophic lupus Others gave histories of tumors of the skin followed by ulceration without tendency to heal Early involvement of the lymph-nodes is frequently seen terminating not unlike tuberculosis

The mode of infection, whether external or internal, has not been determined, but in the forms that produce a skin infection as the first symptom the skin can in all probability be determined as the primary focus In internal cases infection is most frequently seen in the lungs The infection travels by blood- and lymph-streams and in autopsies posted, the internal organs are more or less attacked with lesions and distributions as in tuberculosis In its predilection for organs the two diseases are rather similar-

Most of the previous patients were treated with potassium iodid accompanied with surgery All cases recorded are fatal but one, the first symptom of that being a bone lesion of the ankle The leg was amputated before other lesions developed and the patient is reported alive and well

REPORT OF CASE

The patient was a Japanese, aged 30 years, a farmer by occupation, who had lived in California since coming from Japan in 1909

The previous history was negative except for the diseases of childhood, venereal diseases being denied During the year 1910 he was working in the San Joaquin valley as a teamster in a vineyard January, 1911, he was taken ill, treated for typhoid fever and was in bed for two months During the latter part of this time tenderness developed in the right heel with slight swelling After the fever abated the patient was permitted to be up, the tenderness and swelling remained During the latter part of March, pain and tenderness developed in the left shoulder and later in the left hip Work was resumed, but in a few days he was compelled to stop on account of weakness

In July the patient first came under observation presenting the following symptoms He was fairly well nourished with the appearance of being ill, with pain, tenderness and swelling at the crest of the left ileum near the sacro iliac joint and of the right heel the os calcis and ileum showing bone destruction by the *x* ray There were slight swelling and tenderness over the left scapula and in the right hand over the second and third metacarpal bones Further physical examination proved negative except for a slight tenderness along the colon

Surgery was resorted to, incisions being made along the crest of the ileum and over the os calcis posteriorly, the necrosed bone was curetted and drained. A great deal of pus like material escaped with necrotic bone, which at this time gave no growth on agar, smears showed granular material without leukocytes or bacteria He was in the hospital for six months, during which time similar lesions gradually developed in the left scapula, right metacarpal bones lower end of the left humerus and left tibia These received the same operative treatment with no tendency to close in spite of all after treatment A small nodule developed on the forehead midway between the hair line and the glabella, which grew to be as large as a hazel nut without tenderness or tendency to soften, being firmly attached to the bone but not to the skin There were occasional slight rises of temperature during the later part of the patient's stay at the hospital

Fortunately before leaving the hospital Dr Harry Foster, bacteriologist for the Cutter Laboratories cultured the lesion and found the causative agent to be a mold which was passed *through animals and classified as an oidium* later being identified by Dr William Ophüls of San Francisco as *Oidium coccidioides*

In January, 1912, the patient passed from observation having left for Japan, where he died two months later

The Widal reaction was repeatedly negative and the blood counts showed a slight leukocytosis without increase in the polymorphonuclears No typhoid bacilli could be found by culturing the urine The von Pirquet test proved negative also the Wassermann, but in spite of the latter, salvarsan was given intravenously followed by inunctions of mercury and long continued doses of iodids

ACUTE REFLEX DISORDERS CAUSED BY THE CINEMATOGRAPH

GEORGE M GOULD, M D
ATLANTIC CITY, N J

That the moving-picture shows cause, in many spectators, functional diseases similar to those of eye-strain and ocular labor must have been noticed by every general practitioner and oculist of the cities, and yet, so far as I know, none has publicly directed attention to this important fact. I have had so many patients who have been made sick at these places of amusement that I now ask routine questions to elicit this etiologic factor Not one had thought of the connection, so unobservant are patients in such things, so uninstructed have they been left as regards the use of the eyes and sequent nervous and gastric disorders "What were you doing the evening or afternoon previous to your headache or giddiness, or upset stomach?" "O, nothing at all," is the usual answer, "nothing out of the ordinary, I was at the movies for a couple of hours, and went to bed at once, as I was feeling bad ' General physicians, oculists, opticians, gastrologists and neurologists should therefore be on their guard as to this new and unsuspected cause of certain acute functional disorders of which patients may complain

The symptoms do not in my experience, differ essentially or *greatly from those commonly caused by eye-strain* of any kind, or from any variety of abuses of the eyes The most common, of course, are headache, sick headache, migraine—that is, in one or several of its thousand protean forms A few symptoms that are perhaps more frequent and emphasized than others are intense ocular and cerebral weariness, a sort of dazed, "good-for-nothing" feeling, lack of energy, of appetite, etc , to which almost as frequently may be added, "upset stomach," even vomiting, sleepiness and other similar effects of ametropia, bad spectacles, disuse of good ones, etc

If by wearing accurate corrections of ametropia the patient has previously been made aware of their power to banish suffering of many kinds and intensities, he (or she) at once may think, "My glasses need changing " This of course, may be true, but on consulta on with the oculist his discriminating questions as to the cinematograph will bring out that especial cause as the chief one to be avoided

But if "the movies" are not to blame, or not solely to blame, then the good advice will follow that the correcting lenses will possibly *enable the patient to go to* these shows without the appearance of the distinctive symptoms With uncorrected ametropia, the cinem o-graph will more certainly bring about migrainous and nervous symptoms in the patient than when good glasses are worn, because there is no doubt that the cinematograph pictures put a frightful task on even the least defective eyes, whether glassed or not, but the strain is doubled by bad glasses, or by lack of glasses when they are needed

The retinal and cerebral exhaustion and reflexes at the picture shows have or may have, several more or less distinctive factors The expert who has closely observed and analyzed the morbid results in himself will, of course, at once pounce on the chief source of the mischief—the lack of swiftness and accuracy in the sequence and superposition of the individual pictures thrown on the screen or mirror

The *cinematograph has at least four major pathogenic* faults

1 The fixation-point chosen by the eye and attention is, of itself, frequently unstable and tremulous or jerky in movement This is brought to consciousness by observing attentively a fixed object in the picture, as a post, or tree Both eye and mind are confused by this utterly unnatural movement

2 The individual images of the screen-picture are often superposed so slowly that they are separately perceived instead of being fused into a continuum, or flowing unity There results a swiftly passing series of slightly differing pictures on the retina instead of the desired continuity of one into another Eye and brain have never had to endure such a series of disconnected stimuli as this unendurable fluttering

3 There is a ceaseless and exacting conflict between the parts or locations of the individual pictures demanding the attention of the eyes and of sensation which thus dance from one point to another of the ever-moving points of interest

4 The illumination of the scenes is usually wretched

Progress in the mechanical and photographic mechanisms may improve some of these faults and difficulties, but it is doubtful if, singly or collectively they can be entirely avoided The average rate of exposure of the images or films is about sixteen per second, but if the motions of the scene or objects photographed are rapid, as in galloping horses, for instance, the time of exposure of each image must be of much shorter duration In any case the time of exposure should be so short as to avoid the exhausting labor of eye and brain by the visualization of individual images The poor illumination must be improved, and this should be demanded of the companies

In about a dozen years the business of the cinematograph shows has grown from nothing to its present astonishing capitalization and popularity In our country alone there are said to be between 12,000 and 20,000 moving-picture theaters, i e , one to every 8,000 or 5,000 inhabitants, approximately

The total investment in the business is thought to be about fifty million dollars It is seriously proposed to carry on a large proportion of school-teaching and of medical, hygienic and scientific instruction by means of the cinematograph Goods are bought and sold by means of the pictures, and their uses are multiplying in every department of commercial and social life If it is true that about five million spectators are in daily attendance at the picture-show theaters, the consequent eye-strain injuries and sufferings must be enormous, however conservatively estimated, and there is little likelihood of their exaggeration by hygienists and physicians

401 Oriental Avenue

IRRITATION FROM IODIN AND MERCURY ON THE SKIN

S R KARPELES, M D, WASHINGTON, D C

With the present wide use of tincture of iodin for skin sterilization, the following case and deduction may prove of interest and value [1]

Mrs N applied for treatment for an infected right index finger, Oct 3, 1912 The skin covering the finger and over the anterior and posterior surfaces of its metacarpal bone was disinfected with tincture of iodin A three quarter inch inci sion over the distal phalanx evacuated a little pus, a small drain was inserted into the wound and the finger and hand were covered with gauze soaked in 1 1,000 mercuric chlorid solution A gauze bandage covered the finger, hand and wrist

---

[1] In this connection see THE JOURNAL Nov 2 1912 Department of Queries and Minor Notes, page 1641.

The patient was directed to pour 1 1 000 mercuric chlorid solution over the entire finger every three hours without disturbing the dressing Because of the severe burning pain the dressing was renewed the following day An intense dermatitis with many blisters, some fully an inch in diameter, covered the whole area of iodin sterilization The relief of this most painful complication consumed about two weeks

If a test tube is filled with 1 1,000 watery solution of mercuric chlorid and 2 or 3 drops of tincture of iodin are added, the chemical reaction becomes apparent, red mercuric iodid being formed The latter according, to Wood, "is a powerful local irritant" In the case cited, the watery solution of mercuric chlorid, which saturated the dressings, reacted with the iodin on the skin, converting it into red mercuric iodid

I caution against the combined use of tincture of iodin on the skin and the saturation of the dressings with the watery solution of mercuric chlorid

1120 Fifth Street, N W

CHANCRE DEVELOPING FOUR DAYS AFTER SALVARSAN INJECTION

Melvin Rosenthal, M D, Baltimore

History—February, 1905, J B came to me suffering with an indurated sore on the penis, which had persisted for nearly three weeks There were a double inguinal adenitis, extensive macular eruption and patches in the mouth and on the tonsils A diagnosis of syphilis was made and the patient given the inunction treatment For three years he religiously followed the treatment which consisted of inunctions at first, followed later by mercurial injections and at varying intervals mercury by the mouth

March, 1910, the patient returned with the history that for two years he had done nothing in the way of treatment for his syphilis He had been absolutely free from any symptoms and enjoyed good health He weighed 190 pounds which was 20 pounds more than he weighed before contracting the disease He consulted me as to the advisability of having a Wassermann test, having read of the infallibility of the reaction His mind was unduly occupied with matters syphilitic and he was well informed on recent advancements in the study of the disease The Wassermann report was negative The combination of events prompted me to assure the patient of freedom from any future complications

December, 1910, the patient insisted on a confirmatory Wassermann since reading that "a positive Wassermann is proof positive of the existence of syphilis but a negative result may be accidental or transient" The second report gave a similar negative result

Examination—November, 1911, the patient, presenting the following symptoms, applied for relief For several months he had had periodic attacks of intense pain radiating down the legs He at first attributed them to exertion but since they came on independently of any exercise he abandoned that theory He had also had irregular abdominal pains at times, followed by nausea and vomiting, but unassociated with the presence of food in the stomach The knee jerk was lost on the right side and diminished on the left A provisional diagnosis of locomotor ataxia was made Jan 5, 1912 Since his last visit the patient has consulted Dr Peterson of New York who confirmed the diagnosis of locomotor ataxia and advised the use of salvarsan

Treatment—January 8, an intravenous injection of 0 6 gm salvarsan was followed by slight discomfort, dizziness and headache for several hours January 12 the patient showed a small erosion on the glans penis, which looked not unlike an abraded surface after a vesicle has ruptured Having on a number of occasions seen herpes follow the administration of salvarsan I concluded that the sore was herpetic, and prescribed accordingly January 18 the sore was distinctly indurated and there was some inguinal adenitis, although spirochetes were not found I am frank to admit that I was not disappointed at the failure to find the organism, being satisfied that the sore was an infected herpetic eruption Local treatment of the sore was stopped and on January 22 the edges of the sore were markedly indurated, the inguinal glands were large and a decided macular eruption appeared on the body An examination of the serum from the sore showed undoubted spirochetes and a Wassermann made on the following day was positive. There has been no change in his tabetic symptoms A week later the patient left the city and I have been unable to get into communication with him since that time

The unusual features of this case are first, the development of a disease, presumably of syphilitic origin, in an individual giving repeated negative Wassermann reactions second, that a man suffering from the direct effects of syphilis should contract a chancre and, third, that a chancre should develop four days after an intravenous injection of salvarsan I feel confident that the possibility of faulty technic or other errors in making of the serum reactions may be eliminated, since they were made by a laboratory worker of undoubted skill and ability

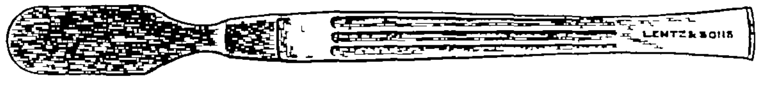
PROSTATECTOMY KNIFE

E H Siter, M D, Philadelphia

Department of Genito-Urinary Surgery University of Pennsylvania

The difficulty in incising the capsule of the prostate with the ordinary sharp pointed knife, and the possibility of hemorrhage from inserting the knife too deeply into the tissue, led me to devise the instrument shown in the illustration



Prostatectomy knife

The object was to have the "belly" or cutting edge of the knife on the end instead of on the side It will be found valuable in dividing the capsule for the suprapubic operation Being flat it is easily guided, and being pointless it reduces to the minimum the danger of puncturing any blood vessel

I find that one incision over each lobe is sufficient to allow me to get the line of cleavage, and I have had no hemorrhage or profuse bleeding since I began its use, I think that the bleeding has been reduced to the oozing which is of minor importance and need cause the operator no uneasiness

2038 Locust Street

Therapeutics

DISTURBANCES OF THE HEART

(Continued from page 21 [illegible])

TRICUSPID INSUFFICIENCY

This rarely, if ever, occurs alone, it is generally a sequence of other valvular defects, and represents an overworked, dilated right ventricle It may, however occur from lesions of the lungs which impede the blood flow through them Such are fibroid changes in the lungs, emphysema, prolonged chronic bronchitis the last stages of pulmonary tuberculosis old neglected pleurisies with cirrhosis or fibrosis of the [illegible] and repeated attacks of asthma — an [illegible] valvular defect or pulmonary circ[illegible] that increases the pressure al[illegible] ventricle

The symptoms are tho[illegible] described under other val[illegible] jugular pulsation, especially evident in the external jugular on the left side. The liver enlarges and may pulsate. There are edemas, dropsies, ascites and perhaps hemorrhages. The heart is enlarged and there is a soft systolic blow heard at the lower end of the sternum. The dyspnea is sometimes very great and cyanosis may be present, especially during paroxysms of coughing.

This lesion of the heart is always benefited by digitalis, but the continuance of the improvement and its amount depend, of course, on the cause of the dilatation of the ventricle. Strychnin is often of advantage. These patients should rarely receive vasodilators, and hot baths, overheating, overloading the stomach and vigorous purging should never be allowed. Sometimes improvement will not take place until ascitic or pleuritic fluid, if present, has been removed.

TRICUSPID STENOSIS: TRICUSPID OBSTRUCTION

This is rare and probably always congenital, and is supposed to be due to an inflammation of the endocardium during intra-uterine life. In early childhood it is possible that it may be associated with left-side endocarditis.

A special treatment of the heart, if any is needed, would probably not be indicated unless there was associated tricuspid insufficiency, when digitalis might be used.

PULMONARY INSUFFICIENCY: PULMONARY REGURGITATION

If this rare condition occurs, it is probably congenital. A distinctive murmur of this insufficiency would be diastolic and accentuated in the second intercostal space on the left of the sternum. It should be remembered that aortic murmurs are often more plainly heard at the left of the sternum. Sooner or later, if this lesion is actually present, the right ventricle dilates and cyanosis and dyspnea occur. Digitalis would therefore be indicated.

PULMONARY STENOSIS: PULMONARY OBSTRUCTION

If stenosis is actually present in this location, the lesion is probably congenital. It might occur after a serious acute infectious endocarditis, but then it would be associated with other lesions of the heart. It has been found to be associated with such congenital lesions of the heart as an open foramen ovale or foramen Botalli, or with an imperfect ventricular septum, and perhaps with tricuspid stenosis — in short, a cardiac congenital defect. The right ventricle becomes hypertrophied, if the child lives, to overcome the obstruction.

The physical sign is a systolic blow at the second intercostal space on the left, but as just stated, such a murmur must surely be dissociated from an aortic murmur if found to develop after babyhood, and it should also be diagnosed from the frequently occurring hemic, basic and systolic murmurs; that is, if signs of pulmonary lesions are not heard soon after birth or in early babyhood the diagnosis of pulmonary defects can be made only by exclusion.

Unless the right ventricle is found later to be in trouble, there is no treatment for this condition. If the right ventricle dilates, digitalis may be of benefit.

ACUTE CARDIAC SYMPTOMS: ACUTE HEART ATTACK

It is not proposed here to describe the condition of sudden cardiac failure or acute dilatation during disease, or after a severe heart strain, but to describe the terrible cardiac agony that occurs, sometimes repeatedly, with many patients who have valvular lesions. These patients may not have the symptoms of loss of compensation. Probably some one or more chambers of the heart become overdistended and act irregularly, or the blood is suddenly dammed up in the lungs, with the oppression and dyspnea caused by such passive congestion; or perhaps it is the right ventricle that is suddenly in serious trouble.

A physician receives an emergency call and knows, if it is not a patient who has hysteria, that it is his duty to see the patient immediately. The friends of the patient all anxiously await the physician's arrival, front doors are often wide open, and the servants and the whole household are in a great state of excitement and anxiety. The position in which the patient will be found is that which he has learned gives him the greatest comfort. If the physician knows his patient, he will know how he will find him. He may be sitting up in bed, he may be standing, leaning over a chair, he may be sitting in a chair leaning over a table or leaning over the back of another chair, but he is using every auxiliary muscle he possesses to respire. He is generally bathed in cold perspiration, the extremities are often icy cold, he calls for air, and to stop fanning all in one breath, he wishes the perspiration wiped off his brow, and nearly goes frantic while it is being done; there is agony depicted on his face, his eyes stare, his expirations are often groaning. Sometimes there is even incontinence of urine and feces, often hiccup or short coughs, perhaps vomiting and possibly sharp pangs of pain in the cardiac region. A patient with these symptoms may die at any moment, and the wonder is that so many times one lives through these paroxysms.

The patient can hardly be questioned, can certainly not be carefully examined, and herein lies the advantage of the family physician who knows the patient and his heart and in whom the patient has confidence. In fact, this confidence which such a patient has in the physician who has more or less frequently aided him in weathering these terrible attacks is alone the greatest boon the patient can have.

The immediate conditions to meet are the rapid, fluttering heart, the nervous excitation and cardiac anxiety, and perhaps the most important of all, the vasomotor spasm that is often so pronounced. Physically we have, then, a heart with leaking or constricted valves; in either case more blood is entering the chambers of the heart than can be expelled in one contraction, while the peripheral resistance due to the spasm of the blood-vessels, because of fear, becomes greater every minute and tends still more to interfere with the peripheral circulation and the complete emptying of the heart of its surplus blood. Owing to the well-known stimulus to distention of hollow muscular organs, the heart contracts faster and faster. Soon by some disarrangement of the inhibitory apparatus, the pneumogastric nerves, the heart loses its governor, and the beats increase to even 150 a minute with irregular contractions, the blood being sent through the arteries with irregular force, as evidenced by the varying volume of the pulse. At this time, with or without cardiac pain, which upsets the rhythm of the heart, the patient becomes frightened at the feeling of impending demise, and the cerebral reflexes begin to add to the cardiac difficulty. The breathing becomes nervously rapid besides that which is due to the rapid heart. The chill of fear is added to the already contracted peripheral vessels, and the surface of the body becomes cold, the extremities sometimes intensely so. Next it seems as if the strongly contracted arterioles begin actually to prevent some of the peripheral circulation, the blood is piled up in the large arteries, and the venous circulation becomes more and more sluggish, while the lips, finger-nails and forehead become cyanotic. Respiration becomes more rapid and deep, the inspiration being as strong as possible with every auxiliary muscle taking part, thus making the negative pressure in the chest aid in bringing the blood back through the veins. Part of the extra respiratory stimulus comes from the imperfectly aerated blood reaching the respiratory center.

Two factors may normally, without treatment, stop these paroxysms, and the "bad heart turn" may be cured spontaneously. The first of these is self-control. If the patient does not lose his head, by an effort of the will he saves himself from becoming nervous or frightened and therefore escapes the result of mental excitement, the increased peripheral blood-pressure from fear does not occur, and in a shorter or longer time the heart quiets down. The physician recognizes this power, and gives his patient immediate assurance that he will soon be all right, the patient who knows his physician immediately feels this assurance and is quickly improved.

The second factor in spontaneous cure of the heart attack is relaxation. The exhaustion from the respiratory muscular efforts together with the drowsy condition caused by the cerebral hyperemia and from the imperfectly aerated blood causes finally a dulling of the mental acuity, and the nervous excitement abates, which, with the exhaustion, gives a relaxation of peripheral arterioles, the resistance to the flow of the blood is removed, the surface of the body becomes warm, the heart quiets down by the equalization of the circulation, and the paroxysm is over.

The part the nervous system plays in this paroxysm is shown by the good result obtained from injections of morphin, even when there is no pain, hence the action of morphin is directly in line with the natural resolution of the symptoms; it quiets the nervous system, causes drowsiness, relaxes spasm, and thus causes increased peripheral circulation, many times this is the only treatment necessary.

During these heart attacks it is more than useless to administer any drug by the stomach, as in this condition there will be no absorption, even if there is no vomiting.

While morphin is generally indicated, as just suggested, a very large dose should not be given, lest the activity of the respiratory center is impaired (it is already in trouble), and undoubtedly death may easily be caused by an overaction of morphin during these heart attacks. The addition of atropin to the morphin will prevent depression from the morphin. Also, atropin sometimes quiets cardiac pain, but it will not steady the heart, may irritate it, and will increase vasomotor tension, although peripheral nerve irritation may be diminished. Hence a fair dose of morphin hypodermatically with a small dose of atropin, if respiratory depression is feared, is a physiologic method of bettering the condition.

In this kind of heart attack a drug that often acts well is nitroglycerin. It may be given hypodermatically in a dose of 1/200 to 1/100 of a grain, or a tablet may be dissolved on the tongue, and the dose be repeated once or twice at fifteen-minute intervals, until there is throbbing in the forehead, which shows that a sufficient amount of the drug has been administered. This headache will generally not last long. In the meantime the peripheral blood-vessels are relaxed, the surface of the body becomes warm, the heart quiets, and the attack is over. To hasten the action of nitroglycerin (that is to equalize the circulation) a hot foot-bath is often valuable. Amyl nitrite may be inhaled with the same object in view, but the action is very intense, the prostration often severe, and unless there is angina pectoris, nitroglycerin is much better.

The symptoms of a heart attack may not be quite those above described, they may be those of sudden dilatation or semiparalysis of the heart, in which the prostration is intense and the patient is unable to sit up, although he may be leaning against several pillows. There is dyspnea, but the patient cannot aid respiration with the auxiliary muscles by holding the arms and shoulders tense or obtaining support from the arms, in fact, the arms are almost strengthless. The surface of the body may be warm, and the arms may be warm except the hands, the feet, ankles and legs may be cold. There is generally more or less cyanosis, although the face may be pale. The finger-nails often show venous stasis. In these cases the blood-pressure is subnormal, the pulse may be hardly perceptible, and there is none of the tension of the body from fear. The patient may be fearful but he is completely collapsed. Such an attack may occur suddenly in a heart that is perfectly compensating or it may accompany general edemas and dropsies.

If the emergency is excessively urgent, the lungs filling up with blood, moist râles beginning to occur, and frothy and blood-tinged sputum being coughed up, venesection may be indicated, combined with proper hypodermatic medication it may save life, and does at times. In fact, a patient who shows every sign of fatal cardiac collapse may be saved.

One of the best drugs to administer to such a patient is an aseptic ergot, injected intramuscularly. The drug of all drugs for future action (as it will not act immediately) is digitalis, and perhaps best, in this condition, in the form of digitalin. (See N. N. R., p. 68.) The dose of German digitalin may be from one-tenth to one-fourth grain, or even more. This dose, or a smaller dose may be repeated in three or four hours, if deemed advisable. Whether digitalis shall be given at all, or how large the dose shall be depends on whether the patient has been taking digitalis in large quantities or not. He may already be overpowered with digitalis. In that case it would be contra-indicated.

Strophanthin, especially when given intravenously, has been found to be a quickly acting circulatory stimulant. The dose of strophanthin, Merck, ranges from 1/500 to 1/200 grain. The intravenous dose of strophanthin, Thoms, is about 1/130 grain. It should not be repeated within a day or two, if at all.

Atropin in a dose of 1/150 grain and strychnin in a dose of 1/40 or 1/30 are valuable aids in stimulating the circulation under these conditions. The atropin should not be repeated. The strychnin may be repeated in three, four or five hours, depending on the size of the previous dose.

Of all quickly acting stimulants none is better than camphor in saturated solution in sterile oil as may be obtained in ampules. Alcohol is absolutely contraindicated in the latter condition. In the former kind of heart attack, vasodilatation from a large dose of whisky or brandy may be of value. The dose should be large to cause immediate increased peripheral circulation, dilatation, and even a little stupefaction of the central nervous system, and it may be effectual in a way not dissimilar to the action of morphin.

BARIUM POISONING AND LOCO-WEED DISEASE

Some time ago[1] mention was made in these columns of the investigations of Dr A C Crawford, then pharmacologist in the Bureau of Plant Industry, on the nature of loco-weed disease This malady is a source of great loss to the stockmen of many of the grazing states of the West Crawford concluded that, in certain regions at least, the inorganic constituents of the plants, especially barium compounds, are responsible for the symptoms of loco-poisoning He asserted that the main toxic features described in stock on the range can be reproduced in rabbits by feeding extracts of certain loco-plants, and that a close analogy exists between the clinical symptoms and the pathologic findings in barium poisoning and those resulting from these experiments

This announcement aroused a wide-spread interest because of its essential novelty Toxic principles in plants had hitherto usually been looked for in the guise of organic compounds, such as the alkaloids and toxalbumins Now, however, the inorganic components of the vegetable forms were called on to explain deleterious effects, and the example which was found to represent them was an element, barium, which had not commonly been taken into account in such relationships If plants readily take up toxic quantities of such elements from soils which yield them, an unexpected and subtle source of danger confronts us

Dr Carl L Alsberg and Mr O F Black, chemical biologists in the U S Bureau of Plant Industry, have reinvestigated this important question[2] They have arrived at the conclusion that the etiologic factor in the loco-weeds which is responsible for the toxicity of these plants in laboratory experiments is not barium Many kinds of plants from the western states and other regions contain barium in amounts of the same order of magnitude as in loco-plants, yet there is no evidence that such plants injure stock on the range

In dried loco-plants the barium is contained in almost insoluble form One might obviously think of the acidity of the gastric juice as an aid to solution, but even extracts prepared by digesting successively with artificial gastric and pancreatic juices contain but slight traces As for the animal experiments, it was shown that there are usually enough salts of calcium, potassium and metals other than barium in appropriate portions of loco-plant extracts to account for death in the usual toxic dose for rabbits Furthermore, similar extracts of alfalfa, which no one charges with special toxicity, may also cause the death of animals in similar dosage

These negative findings of Alsberg and Black are fortified by the newer observations in the field where the conditions pertaining to range animals are met[3] It is now judged that the symptoms and pathology of barium poisoning differ in a marked degree from those noted in loco-poisoning Typical loco-poisoning, according to Marsh, is not produced by barium feeding alone If barium were the cause of loco-poisoning, sulphates which form insoluble compounds of the element would be a logical antidote It appears, however, that experimental administration of magnesium sulphate (Epsom salts) or sulphuric acid in amounts much greater than those necessary to combine with the barium in the loco eaten had no antidotal effect

These newer observations all argue against the specific toxic action of barium in loco-plants The amounts present — rarely more than traces — are too small to prove fatal, and the metal is present in some insoluble form, probably as sulphate or silicate Loco-weed disease needs renewed investigation

TYPHUS FEVER

It has been about seventy-five years since Gerhard, an American physician, convincingly demonstrated on clinical and pathologic grounds the non-identity of typhus and typhoid fevers Up to three years ago our knowledge of the disease stood almost exactly where it was at the time Gerhard first drew attention to its differences from typhoid In the last three years greater advance has been made in our knowledge of the disease, largely through the work of American investigators, than in the previous three-quarters of a century

Last week we discussed[1] some of the factors that have contributed to the wonderful recent advances that have been made in our knowledge of the cause and means of transmission of communicable diseases Reference was made to the fact that without the use of the monkey as an experimental animal our knowledge of typhus would still probably be where it was in Gerhard's time In July, 1909, Nicolle[2] reported the successful infection of a chimpanzee with typhus by inoculation with blood from a case of the disease in man A few months later Anderson and Goldberger,[3] of the U S Public Health Service, by the successful infection of the rhesus and the capuchin monkeys and by showing that these were thereafter immune to subsequent infection, not only confirmed this report but further showed what Nicolle's work indicated, that the fever so induced in the monkey was typhus Following this pioneer work on the disease of Nicolle and his co-workers, and of Anderson and Goldberger, came reports in rapid succession of similar results from Ricketts and Wilder, Gaviño and Girard, and others

[2] Nicolle C Reproduction expérimentale du typhus exanthématique chez le singe Compt rend. Acad d sc. July 12, 1909 p 157

Nicolle, Comte and Conseil[4] were the first to report the successful transmission of the disease by the bites of the body-louse (*Pediculus vestimenti*) Since then this finding has been confirmed by Ricketts and Wilder, and by Goldberger and Anderson, and it may be considered as definitely established that typhus fever is transmissible by the bite of this insect and possibly by the bite of the head-louse The untimely death of Ricketts put an end to his work, but Nicolle and his associates have continued their work on the disease in Africa and have brought out many points of interest Gaviño and Girard, from Mexico, have also reported work of importance, especially in regard to the nature of the virus and the susceptibility of the guinea-pig to the disease

One of the most notable advances in our knowledge of typhus was the demonstration early in the present year by Anderson and Goldberger of the Hygienic Laboratory, that typhus was identical with a disease described by Brill of New York and that, instead of being extinct in the United States as almost universally considered, it has actually been endemic in this country for years[5] Cases have been reported from Brooklyn, Chicago, New York, Philadelphia, and recently at the Southern Medical Association, Paulin reported cases from Atlanta Since the report by Anderson and Goldberger of the identity of Brill's disease and typhus, these workers have continued their work on the disease, and in a recent bulletin[6] of the Hygienic Laboratory have brought together all their work on typhus under one cover The publication is one that will be of the utmost value to students of the disease The last paper[7] in the bulletin is the only one of the articles not previously published, and is chiefly concerned with the question of immunity and the method of transmission

In a study of the susceptibility of the monkey to typhus, the authors found that a large proportion (about 22 4 per cent) of rhesus monkeys possess at least a transient immunity to infection, and that in about 3 5 per cent of their monkeys the resistance amounted to a permanent natural immunity A well-marked typhus reaction confers on the rhesus monkey an immunity that may be present after at least two years It has been found that fever is the only definite clinical index of a typhus reaction in a monkey, but when clearly marked it is ordinarily sufficient to justify a diagnosis of the disease When the fever was slight or its course atypical, in the opinion of the authors it could not be construed as a typhus reaction unless the immunity test proved the animal resistant to infection, but should the immunity test show that resistance has not been conferred, a diagnosis of previous typhus was not permissible The incubation period in about 90 per cent of their monkeys, experimentally infected, varied between six and ten days, and in 103 cases of typhus in the monkey there occurred four deaths Anderson and Goldberger confirm the reports of Nicolle and his co-workers, and of Gaviño and Girard, as to the susceptibility of the guinea-pig to infection with typhus It was found that this animal reacts in essentially the same way to an inoculation of typhus blood as does the monkey and that, as with the monkey, one attack confers immunity to a subsequent infection They found that in a certain proportion of cases rabbits may be infected with typhus by blood inoculation

Typhus-immune serum obtained between the fifth and the fourteenth days of convalescence has protective value when injected simultaneously with the inoculation of virulent material or within forty-eight hours afterward, but immune serum obtained on the thirtieth day of convalescence probably has no appreciable protective influence When immune serum and virus are inoculated simultaneously, immunity to subsequent infection does not result, but when the immune serum is injected forty-eight hours after the virus an immunity, probably active in nature, may take place An attempt to infect a monkey with typhus by means of freshly hatched body-lice, the progeny of presumably infected mothers, was negative In the opinion of Anderson and Goldberger, satisfactory evidence of hereditary transmission of the virus in the louse has not yet been presented Attempts to transmit typhus by means of the bites, or by subcutaneous injection of crushed bedbugs that had previously been allowed to feed on infected monkeys were negative They were also unable to produce typhus in monkeys by the injection of the buccal and pharyngeal secretions from human cases of the disease, and therefore express the opinion that droplet infection plays no part in the transmission of the d ise

Conneff) died from the disease contracted in Mexico and one (Goldberger) was seriously ill. This is another instance of the devotion of men of science to their calling and their willingness to expose themselves to disease and possibly to death in hope of furthering our knowledge. Each year sees additions to this roll of martyrs to medical science, a roll including Lazear, Myers, Dutton, Ricketts, Conneff, McClintic and others.

A REWARD FOR COLONEL GORGAS

Bills have recently been introduced into the Senate and House of Representatives looking to the reward of Colonel Goethals by authorizing his appointment as an additional major-general, and, in the discretion of the President, providing for his assignment as chief of engineers. This proposition suggests several comments, the first of which is that it makes no provision for the reward of Colonel Gorgas. It is also defective in that its provisions depend in part on a contingency which Congress cannot control, because the selection of the chief of engineers is a constitutional function of the executive.

It is now recognized by all well-informed persons that the sanitation of the Isthmus was as essential to the success of the canal construction as was the surmounting of the engineering difficulties, and, of the two sets of problems involved the sanitary problems were newer and along less well-beaten paths than were the engineering ones. While Colonel Goethals is the administrative head of the commission, he and Colonel Gorgas have at present the same military rank. The applications of engineering science to canal construction have no intrinsic precedence over those of medical science to the new and complex questions of tropical sanitation, it would seem, therefore, that there should be little or no difference in the value of the rewards given the two, and it is appropriate that they be provided for in the same act.

There are some other considerations which might well be kept in view when such legislation is under consideration. This work is a great national enterprise which is apart from the usual activities of Army officers, and in no way connected with Army administration. The reward should be in keeping with the national dignity and the magnitude of the enterprise, and should be outside of the routine of Army promotions, so that other officers of the engineering and medical corps who have borne the burden of the routine but important work, without the incentives of increased pay and public applause may not be called on to give their own ewe lamb of promotion as a contribution to the nation's gift.

Again, the officers of the military service are usually compelled by the requirements of their life to live up to their incomes, and when they die their families are left without decent provision. A major-general's widow receives the munificent pension of $30 a month. It would, therefore, be fitting that there should be added to the military promotion in rank a donation of money, as is the custom of the British government so that the generosity of the nation could be applied by the recipient to the needs of those who are dearest to him.

A major-generalship with a cash donation would appear, therefore, the most convenient form of reward for each of these distinguished men, and the act should also provide that after their retirement the President should be authorized to place them on active duty with full pay and allowances whenever their advice or assistance is required on engineering and sanitary questions.

URBAN AND RURAL TYPHOID FEVER

There seems to be a wide-spread belief that typhoid fever is peculiarly a disease of small communities. The regular autumnal increase in this disease in most cities is even referred by some writers to infection contracted during a vacation "in the country." Whatever the importance of "vacation typhoid"—and there is reason to think it has been overestimated—there can be no doubt that, contrary to popular opinion, in some localities typhoid is more prevalent in urban communities.

The incidence of typhoid fever in city and country communities in several New England states has been recently studied by Sedgwick, Taylor and MacNutt.[1] These authors conclude that as far as the state of Massachusetts is concerned typhoid could not be said to be a rural disease in the eighteen years prior to 1908, but was on the contrary distinctly more prevalent in urban communities. In Connecticut a similar condition existed, but in New Hampshire it appeared that there was no marked difference in this respect between rural and urban groups. Before 1890, as these authors point out, typhoid deaths in both Massachusetts and Connecticut were more prevalent in proportion to the population in the country than in the city districts.

It is not difficult to understand these results. The death-rate from typhoid fever depends more on other factors than on city and country conditions as such. A large city with polluted water-supply may maintain a constantly higher typhoid fever rate than the adjacent country towns and rural districts. On the other hand a city with a good water-supply, a pasteurized milk-supply and a proper system of disposing of excretal refuse will to-day almost certainly have less typhoid fever than the smaller communities in its immediate neighborhood. Probably few places in the United States, large or small, will have so low a death-rate from typhoid for the year 1912 as Chicago and Cleveland.

Improper methods of disposing of excreta in the country, with the attendant danger of fly infection, would seem to favor the spread of typhoid fever in rural districts, but a counterbalancing factor is the contact with a large number of persons which is characteristic of city life and would tend to increase the opportunities for infection in cities through the agency of carriers or convalescents. There is no reason why a uniform difference between city and country should be expected In Austria the typhoid death-rate is lowest in communities with less than five hundred population highest in those with from five hundred to two thousand, and then diminishes progressively until the cities with over twenty thousand population have a death-rate but slightly in excess of the small communities with less than five hundred inhabitants

---

[1] Sedgwick, William T., Taylor, George Rodney, and MacNutt, J. Scott: Is Typhoid Fever a Rural Disease? Jour. Infect. Dis., 1912, xi, 141.

In other words, we cannot generalize by asserting that typhoid fever is more prevalent in either the city or the country In some regions the factors that make for infection are more active in the large communities of those regions than the small communities, in others the reverse is true Country or city life itself is in no way determinative of typhoid fever infection, and it is confusing to declare that typhoid is to-day either an urban or a rural disease

ALCOHOL AND RACIAL DEGENERATION

A recent writer on the physiologic rôle of alcohol has well said that most discussions of the subject are frankly partisan and therefore partial An account may be entirely accurate in all its affirmations and yet fail to be just, because of what it leaves unsaid in a matter so full of complex considerations In any event propaganda must be preceded by facts, and these must, in turn, be evaluated in a critical spirit of fairness and with due regard to conflicting possibilities

One of the important and widely discussed phases of the question involves the effect of alcohol on the offspring Records of degenerates, statistics on insanity and other diseases have been gathered in abundance and contributed as evidence in one way or another Statistics are proverbially uncertain unless they are collected with due intelligence and interpreted with reasonable precaution This applies above all to human records, hence it is always gratifying to have observations involving such data substantiated by adequately controlled experiments on lower animals It is with this end in view that Professor Stockard of the Cornell University Medical College, New York, has undertaken an experimental study of racial degeneration in mammals treated with alcohol[1]

Alcohol or any other injurious substance may act as a parental poison to affect the offspring in more than one way Since the quality of the offspring depends on both the perfection of the germ cells from which it arises and the nature of the environment in which the embryo develops, it will be noted that damaging effects may be directed to injure the ovum or spermatozoon before fertilization, or the embryo itself may be affected by being subjected to unusual physical or chemical surroundings In the latter case a substance may so alter the pregnant female as to modify the resulting structure of the developing embryo The possibility of damage arising in this way is emphasized by the fact that a passage of alcohol from the blood of the mother to the tissues of the fetus has been clearly demonstrated The developing embryo or early fetus can show the effects by structural abnormalities of the nervous system, whereas the presence of alcohol in the blood of the later fetus may result in disorders of a mere functional type

In Stockard's experiments alcoholic treatment was given to guinea-pigs by an inhalation method A paternal test was applied by mating alcoholic males with normal females This is obviously the crucial test for an influence on the germ cells, for here a defective offspring must be due to an altered spermatozoon, from which it arose, since the ovum and mother are unimpaired In the maternal test alcoholic females were paired with untreated males As Stockard remarks, here the mother has two chances to injure an offspring, either by producing a defective ovum, or by supplying an unfavorable or diseased environment in which the embryo must develop The greatest chance for impairment lies, of course, in the matings in which both parents are alcoholic

The outcome of these investigations has been convincing in their demonstration that alcohol may readily affect the offspring through either parent Though the animals were never completely intoxicated, they may be described as having been in a state of chronic alcoholism Nine control matings of normal animals in the same group gave nine living litters consisting in all of seventeen vigorous individuals Out of forty-two matings of alcoholized animals only seven young survived and five of these were runts In the paternal tests there were abortions, still-born litters and early deaths, the maternal test resulted much the same, when both parents were alcoholic in most cases the matings resulted in no offspring, very early abortions, or still-born litters The single offspring born living from fourteen matings of alcoholic parents died in convulsions at an early age In general the deaths of these unhealthy young followed symptoms of nervous disorders

Here are data to be reckoned with In pointing to a specific affinity of alcohol for the developing nervous system these newer observations lead in the direction that has been indicated by statistical studies on defective human beings They invest the records of degeneracy in relation to alcoholism with a new significance

SCIENCE AND MEDICINE

In an address[1] delivered at the dedication of the Lane Medical Library of [illegible] ford University the president, Dr David [illegible] reviews some of the changes which med[illegible] ract[illegible] e has [illegible] nced in the past [illegible] ho has wat[illegible] of inf[illegible] were guesswork deserve a broader recognition, especially as they touch on some of the mooted aspects of modern medicine

---

[1] Stockard C R An Experimental Study of Racial Degeneration in Mammals Treated with Alcohol Arch Int Med October 1912, p 369

[1] [illegible]

President Jordan has emphasized in a novel way the undeniable dictum that sound medicine must rest on science As he remarks, science is alike to all men who have grasped its data and its conclusions, art will vary with the personality of those who practice it An art which is not based on knowledge becomes a mystery or a trade It is a mystery when practice is based on some theory of therapeutics which goes outside of human experience for its justification, and those who try to heal without knowledge of the actual conditions with which they deal are of necessity impostors

This is a frank statement, indeed, of the fact that technical knowledge is a fundamental requisite which must be insisted on in those who profess to combat the ills of the human body If this requirement is fatal to any school of therapeutics, it is time that that particular form of fraud should be done away with There need be no hesitation about this natural limit of "medical freedom" The basis of so-called schools of theoretical medicine is a prearranged theory of the treatment of disease They deal with symptoms in default of knowledge of the underlying causes, but when the knowledge is attained all healing methods must rest on the actual conditions rather than the surface indications The preference for one mode of therapeutics over another should rest on science, on which all can agree, rather than on the varying theories of symptoms which furnish the excuse for the varying schools of medicine

Dr Jordan maintains that the form of quackery involved in the "patent medicine" arose out of the notion that a specific disease has a specific cure He pays his compliment to the business by saying that the aggregate result of the "patent medicine" is the building up of gigantic systems of robbery, on the one hand, and a corresponding damage to public health on the other The way out of this domination lies in the better training of physicians and the enlightenment of public opinion

No system of philosophy or cult of religion can help us to find out what is the matter with a disordered organism and thus remove the cause from which the symptoms flow The proposal of the "healers" not to deal with the body because it does not exist, and to 'treat a belief in sickness as you would sin, with sudden dismissal' finds a cold reception at the hands of one who realizes that the whole fabric of modern science and modern civilization is based on the conception of the reality of external things "It is undoubtedly true," says Jordan, "that a serene spirit is a valuable agency in the recovery from disease It is likewise true that suggestion has a mighty potency when it is rightly applied It is a legitimate and recognized branch of therapeutics, which may be destined to have a wide application in the future treatment of disorders of the nervous system But it is likewise true that suggestion heals no broken bones, a spirit unperturbed gives no safeguard against poisoned mosquitoes and the power of the will and the imagination is potent chiefly against disorders of the imagination and the will It does not advance science to doubt the things we know to be true in order to give proof to propositions we know to be false We may, therefore, be certain that progressive medicine will still believe in the reality of the human body and the rational veracity of the world of sense"

Dr Jordan is a strong believer in the importance of governmental action in eliminating unnecessary disease and thereby contributing to the sum of human welfare But governments as they are now framed and conducted do not appeal to him as ideally efficient agencies — they are ruled by traditions and prejudices and often inspired by doubtful motives Perhaps he is somewhat too pessimistic in this direction We must agree with him, however, in the contention that public opinion, the most effective factor in government, must be based on knowledge and molded by safe and sane leaders Here lies the opportunity and duty of the modern man of medicine to join in the conduct of the affairs of the community so that the people will have a reliable guidance where governments sometimes fail

Current Comment

FACTS ABOUT HEROIN

Although heroin (diacetyl-morphin) and its hydrochlorid have been in use but a few years, they have already established themselves among the habit-forming drugs and have become sufficiently conspicuous in this respect to awaken the thinking public to the deplorable results for which they may become responsible These facts of themselves are sufficient to promote a scientific interest in the physiologic behavior of heroin and its fate within the organism A comparison is at once suggested between heroin and the closely related alkaloids morphin and codein (methyl morphin) Aside from differences in the pharmacologic effects of these two substances, they apparently pursue a different path in the body When morphin is introduced subcutaneously it is rapidly excreted into the stomach and, finding its way along the gastro-intestinal canal, may leave the organism to a large extent in the feces Methyl morphin (codein), on the other hand, differs specifically in being eliminated almost exclusively through the kidneys A recent study of the behavior of heroin[1] at the Pharmacologic Institute of the University of Berlin indicates that this drug is ordinarily excreted in large measure by the kidneys as is codein, while a smaller fraction may pass out through the bowel precisely as morphin does There is a pronounced difference between morphin and codein in respect to the development of tolerance, in the case of codein the continued administration of the drug may even lead to hypersensitiveness quite in contrast with its companion alkaloid exhibiting the reverse phenomenon Numerous familiar clinical experiences have demonstrated the development of "heroinism" in human subjects, so that all analogy with codein fails in this direction A case has been described in which a daily dose of 2 8 gm was tolerated Experimental studies on animals show that an increased tolerance is speedily developed In dogs, for example, the narcotic effect which may persist for thirty hours or more with an incipient dose of 25 mg of heroin has been seen to disappear in two hours after five injections of the drug The explanation of the increased tolerance for morphin has been much debated One may conceive of a heightened capacity of the organism to destroy such organic compounds as one possibility, and an increased immunity of the body cells, vague though the understanding of this mechanism must be at present, remains as an alternative explanation Faust has defended the first of these views in the case of morphin, but the fact that toxic doses of the alkaloid have been found in "immunized" animals tends to render such a theory untenable In the case of heroin it appears that with growing tolerance for the drug it is destroyed in increasing proportion in the body, for after a time heroin can no longer be detected in either the feces or the urine under conditions of dosage in which it is readily detected earlier in the course of its repeated administration

THE SUGAR CONTENT OF THE BLOOD

In the study of the abnormalities of sugar-formation and utilization in the body the estimation of the sugar-content of the blood has recently come to take its place in experimental work side by side with the observations on the "overflow" of sugar through the kidneys Indeed, the level of the sugar-supply in the circulation has in some ways become a better index of the mobilization of carbohydrate in the organism than any other determinable factor A rise in the sugar-content of the blood — hyperglycemia — usually betrays itself, as in diabetes, by an elimination of the surplus carbohydrate in the urine Poverty of the blood in sugar, on the other hand, cannot be detected in any such indirect way Blood analysis alone will disclose this condition It has commonly been believed that the circulating sugar, the physiologic importance of which as a form of transport of energy-furnishing material is universally recognized, is to be found solely in the fluid portion of the blood Concordant observations by a number of competent investigators,[1] however, have made it certain that the blood-sugar is present not only in the plasma, but in the corpuscles as well In fact, it now appears that the sugar-content of the corpuscles is as a rule equivalent to that of the circulating fluid in which they are suspended These findings raise the question whether or not the sugar-content of the corpuscles is subject to the variations commonly found in the total blood incident to pathologic or experimental influences which affect the latter — whether or not, for example the corpuscles in diabetic blood also become richer in sugar The correct answer to this query should throw light on the interchange of sugar between corpuscles and plasma Does the sugar enter into the formed elements of the blood by a simple physical process of diffusion? If so, there should be a parallelism in the sugar content of the two factors It is conceivable, nevertheless, that the corpuscles exercise a chemical influence on their contents so that the sugar of these cellular masses is regulated as to quantity and disposition quite independently of the soluble carbohydrate in the environmental medium Recent experiments by Professor Hober[2] in Kiel have shown the latter to be the case In varied types of glycemia the sugar has not been found to be comparably distributed between plasma and corpuscles The most likely explanation for the present is that the blood-cells exercise a regulatory influence on the sugar within them, determining the entrance or exit of the carbohydrate in response to local factors which still await elucidation

EPINEPHRIN FROM THE WHALE

America is a land of large ventures We have become used to hearing of enterprises conducted on a magnificent scale and the ideas which are suggested in an industrial way by the word "enormous" are at times found creeping into the modest domain of science Now we are hearing of investigations of the ductless glands carried out on whales[1] — animals truly affording superb advantages in point of size Their adrenal glands, for example, each weigh considerably more than a pound, thus being about five hundred times larger than those from sheep and fifty times larger than the glands from cattle Structurally the adrenals of the whale resemble those of other mammals, as might be expected The yield of epinephrin is proportional to that hitherto obtained from other animals, so that as much as 1 2 gm of the typical active principle has been isolated from a single whale adrenal gland This is, indeed, an American record

THE CHRISTMAS RED CROSS FILM

Three years ago the Edison Company prepared a special film of a story designed to interest and educate the public in tuberculosis This film was prepared with the cooperation and advice of the National Association for the Study and Prevention of Tuberculosis It was released for use in the moving picture theaters of the country a short time before the Christmas season Many of those interested in the tuberculosis campaign doubted the effectiveness of such a method of publicity, while many persons interested in the moving picture business were skeptical as to whether their patrons would take an interest in a film with so apparent an educational and philanthropic object Much to the satisfaction of all concerned, however, the film proved exceedingly popular, and was greatly in demand Each year since, the Edison Company has prepared a film showing some phase of the tuberculosis campaign in a way to arouse both interest and enthusiasm for the work of the prevention of tuberculosis This year the Red Cross story is entitled "Hope" It tells of a man who does not believe that tuberculosis exists in his county, and who therefore refuses to help in the campaign for its suppression The girl to whom he is betrothed contracts the disease and goes to a New York hospital for treatment because there is no provision in her own town for proper treatment. This arouses the hitherto indifferent business man to the gravity of the situation, with the result that the town builds and equips a tuberculosis sanatorium The lesson of the moving picture film is important, the stimulation of the public to interest and increased knowledge in the disease is much more so

THE CAMMIDGE REACTION IN THE URINE

Recently we took occasion to question the value of the Cammidge reaction, which has enjoyed considerable vogue as a functional test for disease of the pancreas The assumed usefulness of this procedure appears to have become so firmly implanted in the minds of many clinicians, especially the surgeons who are less inclined to exercise a severe critique in matters of chemical import, that a further warning may not be amiss It will be recalled that the reaction is due to the presence in the urine of some unknown substance which yields, on hydrolysis by acid, a compound furnishing a characteristic osazone with phenylhydrazin It was first described in 1904 and has already been the subject of a voluminous literature [1] In confirmation of what we have earlier stated Dr Mayesima of the surgical clinic at the Imperial Japanese University in Kyoto has noted that several substances, such as pentose compounds and glycuronic acid, may be responsible for a positive reaction, the latter being especially concerned in the usual success of the test There is no uniformity in the character of the crystalline osazones obtained Therefore the Cammidge reaction is devoid of diagnostic significance for pancreatic disease It is unfortunate that so promising a reaction must be discarded, but in this respect the test has merely suffered the fate of some of its predecessors Trustworthy functional tests are among the rarities of chemical clinical diagnosis

WHAT'S WRONG?

That champion of the nostrum interests the *Medical Standard* discusses editorially in its December issue the subject of "patent medicines" It commences

> Many people are laboring under the impression that the patent medicine business is being destroyed, thanks to the efforts of *Collier's Weekly* the *Ladies' Home Journal* and THE JOURNAL of the American Medical Association

But, continues our contemporary, this is not the case, "on the contrary, this business is really increasing" Then it quotes figures from a recent Census Bureau bulletin to prove its contention From these figures, it reaches this conclusion

> For every $1,000 paid the doctor, the people pay about $1,500 for "patents" Instead of abusing the druggists or the people who make these more or less "popular" medicines it may be well enough to ask why the people prefer this stuff to our services Possibly there is something wrong with *us*

The *premises* in the case are wrong While the amount of "patent medicines" *manufactured* in this country during recent years may have increased the amount *consumed* by the people of the United States has, to a wonderful degree, diminished Of this, there is not a particle of doubt Lessened home consumption has driven the American "patent-medicine" manufacturer to seek foreign markets — and with success As a result, the American "patent medicine" has become an evil abroad, especially in Great Britain and its colonies While we disagree with the *Medical Standard* on the essential points in its editorial, its closing sentence contains some truth There *is* something wrong with us — the medical profession That "something" we believe to be the pernicious habit of prescribing proprietary mixtures, for the public is awaking to the fact that there is very little difference between the secret or semisecret "ethical proprietary" prescribed by the physician and the secret or semisecret "patent medicine" bought over the counter A further "something" that is "wrong with us" is our easy-going tolerance as a profession, making it commercially profitable for such publications as the *Medical Standard* to exist, for the proprietary evil stands and falls with those medical journals of which the *Medical Standard* is a type As long as the medical profession will tolerate so-called medical journals owned by commercial interests, operated purely for commercial purposes, whose ethics are those of the counting-house and whose owners have no interest in the medical profession aside from the dollars that they may get from it, just so long will the proprietary evil flourish

AGRICULTURE AND PUBLIC HEALTH

The educational value of the bulletins issued by the Department of Agriculture has been repeatedly commented on and commended A list recently received from the Department of Agriculture contains the names of the new publications issued during a single month The list shows the manifold activities of the department and its intimate contact with the daily lives and needs of our farming population Among the pamphlets listed in the monthly announcement are advance reports of field operations of the Bureau of Soils Separate pamphlets contain reports of soil surveys of Jackson County, Ala, Windham County, Conn, Lowndes County, Miss, and Laclede County, Mo Among the new bulletins are pamphlets on "The Manufacture of Butter For Storage," "Feeding Beef Cattle in Alabama," "The Cowpea Weevil," "Forest Fires, Their Causes, Extent and Effects," "The Weed Factor in the Cultivation of Corn," etc Circulars on "Chicken Fat," "Hints to Poultry Raisers," "Directions for Constructing Vats and Dipping Cattle to Destroy Ticks," "Insects Injurious to Mushrooms," "Hog Raising in the South," "Cockroaches and Clothes-Moths," all containing the observations and conclusions of experts on these various subjects, are printed by the department and can be had for a few cents by any one interested The variety of topics covered by the various bureaus and divisions of this department is almost bewildering No one complains that the government is exceeding its functions or that the preparation and distribution of these pamphlets in any way interfere with religious or civil liberty Yet the scientific facts on which these pamphlets are based are exactly the same as those which form the foundation of our present knowledge of disease Chemistry is responsible for our knowledge of the human body and the way in which it works The same chemistry is the basis of soil analysis and modern methods of fertilizing Bacteriology, which gives the farmer information regarding cheese, fermentation and the diseases of animal and plant life, is the source of our knowledge regarding preventable diseases of man If the federal government can analyze the soil of Jackson County, Ala and issue a report on the conditions which it finds, why can it not inspect the physical condition of the citizens of Jackson County and report on the avoidable diseases which prevail there and the best means of preventing them? If the government can publish a report on the bacteriology of cheddar cheese, why can it not inform the people regarding the bacteriology of typhoid fever or cerebrospinal meningitis? If the preparation of a bulletin on forest fires is a proper government function, why is not a bulletin on epidemics of diphtheria their causes, extent and prevention also a legitimate activity of the government? Ignorant or prejudiced obstructionists cannot obscure the issue by talking about "schools of medicine" and "personal liberty" There are no "schools' in the domain of science The dissemination of increased knowledge has always made men free and has never interfered with their liberty

EDUCATIONAL BULLETINS OF STATE BOARDS OF HEALTH

Bulletins issued by many of the state boards of health are being used more and more for the education and enlightenment of the public rather than for the recording of long tables of statistics and formal reports In no section is the increased activity of state health authorities more marked than in the South The bulletins of the state boards of health of three Southern states which recently came in the same mail, are interesting evidence on this point The November *Bulletin of the Mississippi State Board of Health* contains a copy of the proclamation of Governor Brewer, designating November 20 as a health day, and urging the observance of the program of the state board of health on the part of all citizens The state board, cooperating with the state department of education and the Mississippi Federation of Women's Clubs presents a program for use in all of the schools in the state an outline for a course of study on public health by the women's clubs, and a comprehensive article on medical inspection of schools The November *Bulletin of the Virginia State Board of Health* contains an announcement of a lecture bureau established by the board to furnish speakers on public health topics for any community in Virginia which desires to hold a public meeting The announcement opens with the statement, "Settled in its conviction that the education of the people is the surest method of bettering the public health, the board, since its reorganization, has endeavored to place before the citizens of Virginia, in popular form, the tested truths of prevention ' In this statement lies the summary of the entire public health movement The December *Bulletin of the North Carolina State Board of Health* is devoted to the discussion of the liquor problem and public health and the relation of alcohol to public health problems An article on "The Attitude of the Medical Profession to the Use of Alcohol", a friendly talk to boys on the subject "Does it Pay to Drink Whisky?' and an article on "The Relation Between Liquor and the Death-Rate" form the bulk of the pamphlet These three pamphlets are simply selected at random from the copious supply of excellent material which is constantly being placed in the hands of citizens by many of our state boards of health This work cannot fail to enlighten and strongly influence public sentiment, which must ultimately crystallize in better legislation

Medical News

ALABAMA

New Hospitals—Watson Infirmary Decatur, has been opened by Drs W H Watson and Joseph Creer——At a meeting of Anniston physicians December 1, the Anniston Hospital Association was formed with Dr A N Steele as president and Dr T J Brothers secretary The company has rented a building on Marvin Hill for temporary use The institution will be opened to receive patients this month

Medical Staff for Y M C A.—The physical department of the Mobile Young Men's Christian Association has secured agreements from the following eleven physicians of Mobile to serve as members of the staff and to deliver from time to time during the winter, lectures on matters pertaining to health Drs. P O Chaudron, P J Howard, C A Mohr, F H.

Frazer, R C Jones, W C Gordon, A E Maumenee, A. W Metcalf, F M Inge, S F Hale and M T Ganes

ILLINOIS

Personal—Dr Frank H Jenks, Rockford, reported seriously ill, is now said to be improving and about to go home ——Dr E W Oliver has been elected secretary of the Peoria Health Service League ——Dr H L Howell, Bloomington, was operated on at the Brokaw Hospital, December 6, for appendicitis

County Districted for Medical Purposes.—President McCormick of the Cook County Board has arranged to have the county divided into districts, to each of which a physician is to be assigned A committee of seven, with Mr Sherman C Kingsley as chairman, was appointed to take charge and make recommendations

Illinois' Neglect of Epileptics—A special committee of fifty, made up of physicians social workers and others, which has been investigating for several months the condition of epileptics in the state, urges strenuously in its report that the general assembly appropriate sufficient funds to buy about 2,000 acres of unsettled ground suitable for light farming and gardening, where at least 2,000 epileptics might be cared for Efforts in other states have shown that epileptics improve in health where they can be employed out of doors at light work and kept on a carefully selected diet and under scientific care About 10 per cent of such patients have been completely cured and the other 90 per cent have been rendered at least partially self supporting and have thus ceased to be an economic burden to their homes and communities Massachusetts Ohio New York, New Jersey Kansas Connecticut, Texas Indiana and Virginia all have established epileptic colonies and Illinois thus far has been lagging far behind A bill is to be introduced providing for such a colony

Chicago

Quiet Fire in Hospital—A fire in the Monroe Street Hospital, December 9 did considerable damage but caused no panic on account of the care taken by the firemen to work silently

Medical History Society—At the meeting of the Society of Medical History of Chicago, December 12, Dr Jesse S Myer St Louis, gave an illustrated lecture on "Dr William Beaumont"

Benefit for Lynde Hospital—Friends of Lynde Hospital have arranged a benefit concert to be given at the Blackstone Theater, December 27 Lynde Hospital was formerly the medical department of Gads Hill Settlement and is in charge of Dr Katharine B Rich

New Hospital Opened—The South Shore Hospital at Eightieth Street and Luella Avenue recently opened, is a three story brick building with accommodation for forty ward patients in addition to a number of private rooms and is located on a site which has a frontage of 600 feet Drs Axel F A Werelius and Andrew V Dahlberg are respectively surgeon and physician in charge

Personal—Dr P J H Farrell was operated on for appendicitis December 15 and is reported to be doing well ——Dr Robert H Rea has succeeded Dr Frederick B Clark as superintendent of the Chicago State Hospital, Dunning ——Dr Otto F Warning has been appointed a member of the Board of Education ——Dr J N Thorpe was seriously injured in a collision between his automobile and two street cars, December 9 ——Dr Roy H Cox ambulance physician at the Chicago Avenue Police Station injured his knee in a fall while making an emergency call, December 7

INDIANA

Personal—Dr Roy A Hannell Lafayette, has been elected coroner of Tippecanoe County —Dr Charles A Underwood has resigned as health officer of Danville ——Dr Harry M Lamberson Connersville, has been elected coroner of Fayette County and Dr O P M Ford a member of the health board of Connersville

Favors State Commission on Preventable Diseases—The Commercial Club of Indiana, at a meeting December 11, passed resolutions favoring the establishment of a state commission to study the extent of preventable diseases which are said to cost the people of the state not less than $20 000 000 a year and to make a report with recommendations to the general assembly

Public Health Week.—Public Health Week was held in Frankfort, beginning December 10 A health exhibit was made in the Carnegie Library and lectures illustrated by moving pictures were given at frequent intervals The entire proceedings were in charge of Dr C A Zinn, county health officer Dr Benson A Ruddell, health officer of Frankfort, and the county and city superintendents of schools

Epileptics in Indiana.—The annual report of the Board of State Charities shows an increase of 111 epileptics sent to the state institutions during the past year There are now 957 epileptics in public institutions in the state, of whom 543 are men and boys and 414 women and girls Of these, 50 per cent are classed as feeble minded and 38 per cent as insane Only 12 per cent have no marked mental deficiency

Epidemic Diseases—Dr R. C Mackey, health officer of Hobart, on account of the prevalence of scarlet fever, ordered the public and parochial schools and theaters of the town closed for a week, and requested the suspension of worship at all public places and Sunday schools December 1 ——The small pox situation at Jasonville is said to be under control almost all of the cards have been taken down, schools have been opened and public meetings are no longer interdicted

New Laws—The committee on tuberculosis of the Indiana State Medical Society has prepared a law to be introduced during the next legislature to quarantine all people suffering from tuberculosis Public health authorities will be given sufficient legal rights to enforce the law The State Board of Health has had a public hygiene bill written which will be introduced in the legislature at the request of the Travelers' Protective Association It provides for fine or imprisonment for the proprietor of any public building such as hotels, cafes boarding houses etc, that is maintained in an unsanitary condition This bill defines what are unsanitary and unhealthy conditions Other bills have been prepared providing

1 For a civil service for county health officers
2 For the removal of the pathologic laboratories of the state from the state house
3 For empowering the state board to pass on all school house plans
4 For the establishment of a department of sanitary engineering
5 For the enlargement of the capacity of the State Pasteur Institute
6 For the enlargement of the executive offices of the state board at the state house
7 For the cooperation with other states in work on occupational diseases bad housing etc
8 For the control and eradication of cattle tuberculosis
9 For the restriction of the use of cocain to physicians and dentists
10 For the prohibiting of fraudulent advertising of medicinal preparations intended to be used for cure of diseases of man or animals

IOWA

Small Pox.—About thirty families of Ponca are in quarantine because of the prevalence of small pox, which, as is often the case was at first taken for chicken pox.

Personal.—Dr W O Smouse Des Moines has started for Germany ——Dr W H Newlon, Fort Madison, has gone abroad ——Dr Charles Ryan, Des Moines, who was operated on for appendicitis at Lakeside Hospital, Cleveland, November 25 is reported to be doing well ——Dr F J Will has resigned as local surgeon to the Chicago and Northwestern System at Des Moines and has been succeeded by Drs O J Fay and A C Page ——Drs G B Little and Bertha McDavitt Burlington were thrown from the automobile in which they were riding and painfully injured ——Drs W L. Bierring William Pearson and Erwin Schenk have been appointed as an advisory medical committee to the school board of Des Moines ——Dr J C Powers, Hampton, who is under treatment in a hospital in Chicago for an infected wound of the hand is reported to be improving

KENTUCKY

New Officers—Henderson County Medical Society at Henderson December 10 *president*, Dr R H Moss, *secretary treasurer* Dr P Ligon

Explosion in Sanatorium—A boiler exploded in the laundry and kitchen building of the Hazlewood Sanatorium near Taylor Boulevard Louisville, November 25 and the building was burned to the ground No one was injured and it was not necessary to remove the patients from the institution

Personal—Dr John G Cecil has resigned as a member of the executive committee of the medical department of the University of Louisville, and has been succeeded by Dr J Garland Sherrill The committee is now composed of Drs W I Grant J B Marvin, Clint Kelly, J M Ray, W H Wathen and J M Bodine, besides the new member

Scovill's Successor—The trustees of the State University of Kentucky confirmed the selection of Dr Joseph H Kastle for director of the Agricultural Experiment Station and dean of the College of Agriculture. Dr Kastle was formerly in the government employ in the Bureau of Animal Industry and had the unanimous endorsement of the entire force of the experiment station for the position of director to succeed Professor Scovill

Hospital Notes—Beginning December 1, Speers Hospital, Dayton, will become the annex hospital for the Chesapeake and Ohio Railroad Heretofore employees of the company who required treatment have been obliged to go to hospitals at Clifton Forge or Huntington, W Va——The Martinsville Sanatorium, Louisville, was damaged by fire to the extent of $10,000, October 30——The new hospital at Paris, Ky, will be ready for occupancy by December 1——Highland Hospital, the first hospital to be established in the mountain region of Kentucky, has recently been dedicated The establishment of this hospital is the result of the efforts of Rev E O Guerrant, mountain evangelist——Drs J N and A T McCormack and Lillian H South have sold St Joseph's Hospital, Bowling Green, to Dr T O Helm This includes the franchise, nurses' training school, operating outfit and the entire equipment of the institution

MARYLAND

New Officers—Calvert County Medical Society president Dr O D Simmons, Bowens, secretary, Dr John W Leitsch, Huntingtown

Hospital Opened—The Allegheny Hospital of the Sisters of Charity, Cumberland, with accommodation for one hundred patients, was opened for inspection December 9

Academy Introduces Inspection.—The Academy of Medicine of Cumberland has formally endorsed the recommendations of Governor Goldsborough at the semi annual meeting of the Medical and Chirurgical Faculty of Maryland, that a state sanitary and a state dairy inspector be appointed, with deputies in each county

Personal—Dr Ralph W McDowell, Annapolis was seriously injured in Philadelphia, November 29, in a collision between the taxicab in which he was riding and a trolley car——Dr William P E Wyse, Pikesville, has been awarded a verdict for $2,000 on account of injuries sustained by him two years ago in a collision between automobiles

Baltimore

New Officers—University of Maryland Medical Society, December 10 president, Dr Nathan Winslow, secretary, Dr A L Fehsenfeld

Measles on Steamer—The North German Lloyd Steamship *Main* arrived at Baltimore, December 7, with thirty seven cases of measles and twenty three suspects

Sanitary Equipment Adopted by Railroad—The Baltimore and Ohio System has equipped its passenger trains and stations and lavatories with sanitary paper roll towels It has also abolished the public drinking glass, replacing it with individual cup service

Personal.—Dr John J Rennington, who was severely injured in a fall from a street car, December 9, has returned home——Dr George C Wegefarth was operated on for appendicitis December 12, at the Church Home and Infirmary——Drs Anna D Abercrombie and John Travers have been appointed medical inspectors under the child labor law——The following have been appointed as the advisory board by the Home for the Widows and Orphans Cardinal Gibbons, Hon Henry Stockbridge and Drs Lewellys F Barker, Hugh H Young, Hon W T Finney, Randolph Winslow, Charles O Donovan, T C Gilchrist, D W Cathell and J G Jeffers

MASSACHUSETTS

New Officers—Somerville Medical Society, December 5 president, Dr E D Pillsbury, secretary treasurer, Dr Allen H Blake, both reelected

Personal.—Dr James A Honeij, Cambridge, has been appointed by the State Board of Charities assistant physician at the Leper Colony, Penikes Island He will have the use of the laboratory of the Harvard Medical School and will make a study of the fifteen cases of leprosy now on the island——Dr Franz L. F E Pfaff has resigned as professor of pharmacology and therapeutics in Harvard Medical School and will take a vacation of two years——Dr Louis M Spear has been appointed physician in chief of the Peter Bent Brigham Hospital, Dr Edward P Richardson, surgeon, and Dr Charles F Painter, orthopedic surgeon

Hospital Notes.—At the annual meeting of the Boston Floating Hospital, November 7, Dr Samuel H Durgin was elected a trustee and Dr Henry C Marble, resident physician——Ground was broken recently for the new St Elizabeth's Hospital Brighton The ceremonies were in charge of Cardinal O'Connell, president of the hospital corporation——A fire in the store room of the Emerson Hospital Forest Hills, destroyed many valuable medical books——The new buildings of the Talitha Cumi Maternity Home, Forest Hills, were formally opened, October 20 by Bishop Lawrence The home is under the management of Drs I M Hastings and F M Plummer Dr Elizabeth Ritter Brookline is resident physician and Dr William F Wesselhoeft, consulting physician——The Pittsfield Antituberculosis Association has awarded the contract for building a new central house on the Roberts Camp at West Pittsfield, to cost $15 000——At the rummage sale for the benefit of the Boston Babies' Hospital, October 24, more than $4 300 was realized for the institution——The Women's Charity Hospital Club has voted to change the name of its hospital to the Massachusetts Women's Hospital——The executive committee of the Burbank Hospital, Fitchburg, has been authorized to build a tuberculosis hospital at a cost of about $28,000——The new Melrose Hospital was damaged by fire recently to the extent of $1,500——The new Marlboro General Hospital was opened without formal exercises, December 6 The building, which has cost $57 000, is of concrete construction and consists of an administration building and two wards The institution will accommodate about thirty six patients

MINNESOTA

Personal—Dr J Frank Corbett city bacteriologist of Minneapolis, has resigned——Dr Lattan A Crandall has been reelected president of the Minneapolis Child Welfare Association

Norwegian Hospital—The Hoyme Hospital Association has purchased a site for the institution at Twenty Sixth Avenue West and Fourth Street, Duluth on which it proposes to erect a hospital to cost about $50 000 Dr H N Hovde is vice president of the association and Drs J M O Tufty and O J Heimark are directors

Free Eye Dispensary—The University of Minnesota Free Dispensary has created an optical department which will be under the charge of Dr Frank C Todd of the medical faculty

New Officers—Southwestern Minnesota Medical Association at Luverne, November 12 president Dr L L Sogge, Windom, secretary treasurer, Dr Emil King, Fulda Windom was selected as the next place of meeting——Southern Minnesota Medical Association at Mankato, December 4 president, Dr A B Stewart, Owatonna, secretary, Dr W T Adams Elgin——Midway Medical Association met for organization December 9, Dr Frederick E Leavitt, St Paul, acting as chairman

MISSOURI

District Health Society Organized.—Representatives of the health departments of the twenty six counties and cities of western Missouri designated as the seventh district, met in Springfield, November 21 and organized a district society electing Dr J M Billings, Lebanon, president, and Dr W M West, Monett, secretary

Personal.—Dr Harry Czarlinsky Kansas City, has been elected coroner of Jackson County—Dr George P Pipkin Kansas City, underwent operation for appendicitis at the Kansas City General Hospital, November 7——Dr W L Gist city physician of Kansas City has been placed in charge of the ambulance corps, National Guard of Missouri, with the rank of captain

Tuberculosis Hospital Districts—Buchanan County Tuberculosis Hospital District is the first to be organized on the law passed by the last legislature The governor has appointed the following as commissioners for the district Colonel James H McCord, Mr George Schneider, Mr Eugene Westheimer, Dr Daniel Morton St Joseph and Colonel J A Corby The establishment of the district assures care for those suffering from tuberculosis as soon as the board can get the necessary agencies at work

St Louis

Diphtheria—The local board of health reports at least four hundred cases of diphtheria in addition to a great number of suspected cases

New Officers—St Louis Medical Society, November 25 president, Dr Louis H Behrens, secretary, Dr Frederick C L Kuhlman (reelected)

Personal.—Dr D F Rice was slightly injured in a collision between the automobile in which he was riding and a trolley car December 2——Dr Louis R Padberg has been elected coroner of St Louis, vice Dr Jules Baron

Diphtheria Epidemic—The discovery of twenty three cases of diphtheria in the industrial school has caused the isolation of the patients in the contagion hospital, and the prophylactic administration of antitoxin to 318 children

NEW YORK

Tuberculosis Hospital for Saratoga County—The application of the supervisors of Saratoga County for permission to establish a hospital for the treatment of tuberculosis in the town of Providence, Saratoga County, has been approved by the State Commissioner of Health

Personal—Dr William T Pearson has been elected superintendent of the Glenridge Sanatorium to succeed himself——Dr and Mrs George H Dill, Fort Plain, have started for California——Dr Maurice J Lewi has resigned as secretary of the State Board of Medical Examiners and Dr Otto Von Huffman of New York City has been appointed in his place

International Water Pollution—The November bulletin of the State Department of Health calls attention to the fact that a question has arisen with reference to the extent of the jurisdiction under the treaty between the United States and Canada, whether the International Joint Commission may properly consider pollution of waters on either side of the international boundary line, which by diffusion or otherwise, do not extend over and pollute the waters on the other side of the boundary line When this question of jurisdiction is settled, the State Commissioner of Health will appear before the commission by invitation at a hearing to be held in Washington and will explain the attitude of the State Department of Health with regard to the pollution of streams, and will present a report showing the action of the state on all applications for permission to discharge sewage into boundary waters between New York and Canada

New York City

Personal.—Dr Edgar G Janeway, who died Feb 10, 1911, left an estate appraised at $481,500——Dr M Rabinovitz, adjunct gynecologist to the Beth Israel Hospital, has been appointed visiting gynecologist to Sydenham Hospital Richard Lake, F R C S, lectured before the Section on Otology of the New York Academy of Medicine December 14 on "The Clinical and Therapeutical Aspects of Vertigo"

To Raise Money for Bronx Hospital.—An industrial exhibit is being held in the Grand Central Palace for the benefit of the Bronx Hospital to which the admission fee is one dollar Each ticket entitles the bearer to one dollar's worth of goods It is said that $500,000 worth of goods will be distributed The new Bronx Hospital, which is to supplant the present institution, will cost about $350 000 and will contain over 200 free beds The dispensary will be equipped to treat about 100,000 patients a year

Letchworth Village Contracts Ready to be Let—Letchworth Village, an institution for the segregation of epileptics and feeble minded for which the state has acquired a large tract of land at Thiells near Haverstraw, is to be begun in the near future The plans for the institution have been completed and the group of buildings to be constructed consists of four dormitories, an attendants' home a dining hall, a power plant and a storehouse At the last session of the legislature $457,000 was appropriated for this purpose Ultimately the village will consist of six groups of buildings, each consisting of eight dormitories, an industrial building, and a school house Each group of buildings will have accommodations for 500 inmates

Endowment for Work Among Defectives—The new Clearing House for Defectives which was established recently in connection with the Department of Charities has been doing its work with the aid of volunteer surgeons associated with Dr Max G Schlapp Commissioner Drummond presented the needs of this work at a recent meeting of the Woman s Municipal League and as a result an endowment sufficient to secure its permanency and to enable it to open all necessary records and make investigations has been secured through the generosity of Mrs W K Vanderbilt, Mrs August Belmont, Mrs Hewitt and Mrs Seligman An important part of the work will be the creation for the first time in this country of a systematic record of all defectives known to be at large

NORTH CAROLINA

Work of the Hookworm Commission—The hookworm commission, operating under the direction of Dr J A. Ferrell, assistant secretary of the State Board of Health, is composed of six physicians eight microscopists and one stenographer Up to December 1, 148,993 examinations had been made in the state and 98 730 persons had been treated The Rockefeller Commission spent in this work $20,000 and the State Board of Health $6,000, while the sixty counties in which the commission has operated have contributed approximately $15,000 to provide accommodation for the hookworm laboratories, advertise the work that is being done and pay for the medicines used Usually from five to eight dispensaries were established in each county and the work of examinations and treatments occupied about six weeks Public health pamphlets are distributed and it is believed a great impetus to general sanitation will be the result of the work Continued observations verify the earlier suggestion of Dr Stiles that the disease is found much more frequently in sandy districts than in clay subsoil For instance, the examinations of the suspects in Richmond County show 38 per cent infection as contrasted with 17 per cent in Buncombe County

OHIO

Hospital Notes.—Memorial Hospital, Elyria, will hereafter receive annually an appropriation of $6,000 from the city instead of $5,000, as heretofore——St Elizabeth's Hospital, Youngstown, opened to receive patients December 8

Hoover in Des Moines.—Dr C F Hoover, Cleveland, was the guest of hono of Des Moines (Ia) Pathologic Society at its November 15 meeting and delivered an address on "Respiratory Ventilation of the Lungs in Health and Disease"

Small Pox.—The illness of ten patients in the State Hospital, Toledo and of five employees, which had been diagnosed as chicken pox, has been pronounced small pox and the patients and 100 other patients and employees who had been exposed are in quarantine——Seven cases of small pox are reported in Zanesville and a theater and all moving picture shows have been ordered closed

Personal.—Dr J W Piper, Bethesda, who has been seriously ill with pneumonia, is reported to be improving——Dr C H Bailey, East Liverpool, has been appointed tuberculosis inspector with jurisdiction over all potteries in East Liverpool Wellsville, Chester and Newell——Dr J W Costolo, superintendent of the District Tuberculosis Hospital, Lima, has resigned and will resume practice in Sidney——Dr J W McKemy, Dayton, has been elected coroner of Montgomery County——Dr G O Maskey, Upper Sandusky, has been appointed local surgeon of the Columbus, Hocking Valley and Toledo Railroad——Dr W M Buchrer, Cleveland, has been appointed superintendent of the new tuberculosis hospital, Warrensville, Cleveland, which is to be opened January 1——Dr R H Grube, Xenia, has been elected dean and Dr P R Madden Xenia, secretary of the Ohio Soldiers' and Sailors' Orphans' Home——Dr A. Delaplane, formerly physician at the State Penitentiary, Columbus, has been appointed assistant medical examiner of the Pennsylvania System between Chicago and Pittsburgh, with headquarters at Fort Wayne, Ind——Dr H T Phillips, Athens, coroner of Athens County has been elected probate judge of the county and will take office, February 9, next

WEST VIRGINIA

Society Honors Governor-Elect—The Medical Society of McDowell County, at its last annual session, December 11 elected Dr J Howard Anderson Marytown, president and Dr S D Hatfield, Iaeger, secretary The society adopted resolutions appreciating the confidence reposed by the people of the state in Dr H D Hatfield, Eckman a member of the society, in electing him governor—the first time a member of the medical profession in the state has been so honored, congratulating Dr Hatfield on the distinction conferred on him and on the reflected glory brought on the medical profession of the state and his county society, and pledging him hearty support during his administration, with special reference to state wide hygiene and sanitation

GENERAL

Prize Offered for Work on Diabetes—The local medical society at Carlsbad has offered $1,000 (5,000 crowns) for the best work or works on 'Treatment of Diabetes Mellitus with Special Reference to Balneotherapy" Competition is open to physicians of all countries, and any language may be used All communications should be addressed to the Vereinigung Karlsbader Aertze, Carlsbad, Austria The jury consists of von Jaksch of Prague Lüthje of Kiel, Ortner of Vienna, Schmidt of Innsbruck and Dr Ganz Articles must be received by Dec. 31, 1913

American Society for Physicians' Study Travels—Philadelphia has taken the lead in the organization of a society with this name patterned after the Deutsches Zentralkomitee für ärztliche Studienreisen This German organization, it will be remembered, sent a party throughout the United States, in connection with a visit to the International Congress on Hygiene and Demography at Washington It was the fourteenth annual tour of the kind The party and its trip were described in The Journal, August 24, page 662, August 31, page 731, September 7, page 812, and in subsequent issues The success of the trip and the interest taken in the entertainment of the members by members of the medical profession in the various cities visited have awakened a desire for a similar organization in the United States At a subscription dinner in Philadelphia, December 7, a committee was appointed to organize the American Society for Physicians' Study Travels Dr James M Anders was elected chairman Speaking for his committee, Dr Anders asks all American physicians interested in this proposition to correspond with him at 1605 Walnut Street, Philadelphia Clinics can be arranged in advance, lectures prepared and visits made to the best hospitals and health resorts, with the assurance of a hearty welcome from the leading medical men of the localities visited Dr Anders seeks to have this society represent the American medical profession with all the medical centers represented in its membership So many physicians go abroad each year that the prospect looks bright for a successful organization in this country, and Dr Anders will be glad to hear from all who are able to consider the matter at all seriously In this connection it should be stated that tours are being arranged in connection with the International Medical Congress at London, August, 1913, by Dr Richard Kovacs, New York City, and by Dr C W Fassett, St Joseph, Mo

LONDON LETTER

(From Our Regular Correspondent)

London, Dec. 7, 1912

International Congress of Medicine

The International Congress of Medicine which is to be held in London next August will be one of the largest international gatherings held in this country for many years It is expected that at least five thousand physicians will be present as delegates Of those about two thousand will probably come from Great Britain and other English speaking countries, about one thousand from Germany, one thousand from France and one thousand from other countries For its largest meetings the congress will assemble in Albert Hall There are twenty six sections and subsections, most of which will meet daily, the meeting places must therefore necessarily be somewhat scattered in various parts of London The forthcoming congress will probably surpass all its forerunners in numbers It will certainly show a marked advance on the last meeting in London in 1881, the seventh meeting of the congress, when the delegates numbered about three thousand The present is the seventeenth meeting The increasing specialization of medicine is illustrated by the fact that the sections for the discussion of particular branches of medicine have grown from fifteen in 1881 to twenty six at the forthcoming meeting The congress of 1881 over which Sir James Paget presided was notable for the presence of Huxley, who spoke on the subject of heredity, and, of Pasteur While the program of the coming congress does not contain any names so great as these, nearly every distinguished man in British medicine is among the officers, presidents of the sections, or contributors of papers The congress will be presided over by Sir Thomas Barlow, president of the Royal College of Physicians The general addresses to the full congress in the Albert Hall will be given by Professor Chauffard of Paris, on medicine, Geheimrat Professor Paul Ehrlich of Frankfurt, on pathology, Mr John Burns, M P, on public health, Prof Harvey Cushing of Harvard University, on surgery, and Mr W Bateson, F R.S, on heredity The proceedings in the sections will be conducted mainly in English, French, German and Italian, but, with the assistance of interpreters, the delegates may speak in any language Some of the subjects to be discussed are of more than professional interest, such as the psychology of crime, which is to be considered at a joint meeting of the forensic medicine and psychiatry sections The causes of epidemic diseases and the effects of dust in producing diseases of the lungs are to be considered in the section of hygiene The forensic medicine section will discuss the causes and prevention of suicide, and the tropical medicine section the subjects of plague and beriberi To promote imperial feeling the British committee has appointed on the various committees representatives of the profession in the oversea dominions When it was first proposed to hold the meeting in London the invitation was given on behalf of members of the profession in Great Britain only Many representatives of Canada, Australasia and India have now been nominated and the whole empire will now play the part of host to the congress A fund is being raised to meet the expenses of the meeting, which are expected to amount to $40,000

The National Insurance Act Decision of the British Medical Association Still in the Balance

Though there are only six weeks before the medical benefits of the national insurance act come into force, the British Medical Association has not yet given its decision whether to work the act or not The following concessions were made by the Chancellor of the Exchequer, Mr Lloyd George, in his final interview with the deputation appointed by the British Medical Association The first point raised was as to the scope of the services which the insured person might demand The reply is 'The insured person cannot demand services beyond those which every member of the panel may reasonably be expected to give The treatment which the practitioner undertakes to give is that which can properly be undertaken by practitioners of ordinary competence and skill" It was pointed out that a physician may have acquired special skill in some branch and be able to perform an operation which no one without special skill could undertake The insured person cannot require that as part of his medical benefit To decide whether any disputed case comes within the agreement it is proposed that the local insurance committee (consisting mainly of laymen) shall, if necessary, refer it for decision to a court of reference set up for the purpose by the government Certain duties, although coming within what will be required as medical benefit, have been distinguished for some time as "extra" Examples are minor operations, setting fractures, night visits etc Payment of these extras depends on the method adopted for distributing among the physicians in each area the amount available for that area Some districts may decide on a capitation payment, each physician receiving so much per head for all risks whereas others may set aside a portion of the total amount available to provide a pool out of which the fees for extras would be paid As a deterrent against unreasonable demands the deputation asked that the physicians should be allowed to make a small charge for night and special visits This was refused as impossible, but it is proposed to meet the point by giving the insurance committees power to fine insured persons, or in the case of repeated offenses to suspend from medical benefit those who make unreasonable demands on the physicians attending them On the question of mileage for country physicians (mentioned in a previous letter) the government considers the capitation rate offered sufficient, as these physicians are allowed to dispense their own medicines and thus receive the profits which in the case of the city physicians go to the pharmacists The government, however, recognizes that in some parts of the country exceptionally sparsely populated the physicians would be at a disadvantage Parliament will therefore be asked to provide a small fund for such areas Physicians will be required to keep only such records as will furnish information as to the incidence of disease It is pointed out that no regulations could be framed to exclude the insurance committee from power to consider complaints against a physician and that for the protection of physicians a provision had been inserted in the regulations a complaint should not be considered by the insurance committee until it had been sifted in private session by a body in which the physicians and the insured would be equally represented The government has acceded to the request that the medical members of each insurance committee shall constitute not less than one tenth of the whole

THE ACTION OF THE BRITISH MEDICAL ASSOCIATION

The report of this final conference with the Chancellor of the Exchequer has been considered by the council and several protracted sittings, one lasting as long as eleven hours, have been held As stated in previous letters there are two parties on the council, an extreme and a more moderate one It seems, therefore that under the circumstances the council could not give any lead to the association The intention to send with the report of the final interview with the Chancellor a covering letter to the divisions of the association has therefore been abandoned Meetings of the divisions are about to be held all over the country to determine finally whether the association will work the act o To ll physicians, whether members of the a n been invit

An organiza
formed The
consisting la

act Their number appeared to be very small, but the recent concession of the government has, as anticipated, increased the number of those willing to serve Moreover, a certain political element exists in the situation It is quite true that the majority of physicians, whether liberal or conservative, opposed the act on purely professional grounds and some of its most vehement opponents have been prominent liberal supporters of the government At the same time the conservative press has tried to make as much party capital as possible out of the dissatisfaction of the profession and at the meetings of the association the intensified virulence of those who were opposed to the government on political, as well as professional grounds, was evident A marked example is the president of the association, Sir James Barr, into whose unmeasured denunciation of the act the political bias so strongly entered that protests have been made by members of the association On the liberal side there has been little evidence of party feeling entering into the controversy Dr Esmonde, an Irish member of Parliament, who was once in general practice, has announced, however, that the government has met the physicians fairly and he has invited communications from those willing to work the act He claims to have received a large number of responses In consequence of the Home Rule question the members of the Irish party are strong supporters of the government While there are no grounds for saying that Dr Esmonde is not doing what he honestly believes to be in the interests of the profession, one cannot help feeling that the motive of countering the attack made by the conservative party against the act enters into his action At the eleventh hour there has also been started a new association termed "The National Insurance Practitioners' Association," which has sent a circular to every physician asking if he is willing to serve This association recognizes the good work which has been done by the British Medical Association in securing better terms from the government, but in consequence of these terms it holds that the undertaking not to work the act except on conditions approved by the British Medical Association is no longer binding Before issuing this circular they would have waited until the council of the British Medical Association had reported and an opportunity been given them of recording their votes, but a circular sent out to the members of the Westminster provisional medical committee of the association has made this impossible This circular states that "the number of doctors willing to work the act on any terms must be very few indeed" and that "it is only on matters of detail as to the best method of carrying on a campaign of resistance that differences exist" The founders of the new association say that it is their duty to the public as well as to themselves to take service and that they have formed the new association, not out of any disloyalty to the British Medical Association, but for the protection of their own interests To say the least, it seems unfortunate that they did not delay their manifesto until the decision of the association has been given The time for making arrangements for the working of the act, however, is now very short

PARIS LETTER

(From Our Regular Correspondent)

Paris, Nov 22, 1912

The Fight Against the Decrease of Population

A decree has been issued for the formation by the minister of finance, M Klotz, of an extraparliamentary commission (including several physicians) for the study of national, social and fiscal questions concerning the decrease of population in France and of seeking the means of remedying the condition For several years the legislative chambers and successive governments have considered the problem, but up to the present nothing has been accomplished except half way measures, because the fiscal side of the question has been neglected

The Lowest Pulmonary Capacity Compatible With Life

At one of the recent meetings of the Académie des Sciences, Drs Léon Bernard, A Le Play of Paris and Charles Mantoux of Cannes reported the outcome of their researches on the lowest pulmonary capacity compatible with life They employed a special technic suggested by the treatment of pulmonary tuberculosis by means of artificial pneumothorax, following the procedure of Forlanini The principle was to immobilize the lungs in such a way that their movement was restricted to the lowest limit compatible with the maintenance of life This immobilization was accomplished by means of nitrogen the resorption of which is negligible This gas is injected at first into the right pleura to the point of complete immobilization, and then into the left pleura to a certain limit where the experiment stops Then skiagraphic and fluoroscopic examinations are made By these means different factors can be determined, such as the quantity of gas injected and the volume and weight of the lungs, which permits by a simple calculation a determination of the lowest capacity of the lungs compatible with life This has been found to be about one sixth of the total lung capacity

The Struggle Against Alcohol

As I have told in a preceding letter, the Chamber of Deputies by a vote of 361 to 155 postponed the passing of the law voted by the senate to limit the number of liquor licenses (The Journal, March 16, 1912, p 794) This vote has caused much disappointment The Académie de médecine and a large number of medical societies have protested against the postponement of this reform, the most urgent of all The Ligue nationale contre l'alcoolisme, presided over by Professor Debove, formerly dean of the Faculté de médecine of Paris, has issued an appeal to French women to initiate one of these movements against which political assemblies can fight only in vain To combat the distillery, that formidable financial trust supported by 400,000 tavern keepers, the league invites French women *en masse* to sign a petition which cannot fail to impress the Chamber of Deputies

Prizes Awarded to Finlay and Agramonte

Among the prizes offered for competition by the Académie des Sciences the most important is the Bréant prize (100,000 francs $20,000) for the cure of Asiatic cholera Naturally this prize has not been awarded this year, but from the income from the foundation the academy has awarded a prize of $500 (2,500 francs) to Dr Carlos J Finlay of Havana and another of equal value to Dr A Agramonte of Havana for their work on the rôle of the mosquito in the propagation of yellow fever

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, Nov 22, 1912

Personal

Professor Gumprecht of Weimar has been appointed to deliver a brief course of lectures on social and economic questions of interest to physicians

On November 20, Professor Stieda of Königsberg celebrated his fiftieth anniversary as dozent

Professor Czerny of Strasburg has accepted the call as successor of Heubner

Practice of Foreign Physicians in German Watering Places

In spite of the fact that persons who are not licensed in Germany are not allowed to call themselves physicians or to use any similar title, for many years foreign physicians, mostly Russian, have been carrying on an extensive practice in Germany, particularly among their own countrymen in Berlin and the cosmopolitan watering places On motion of the medical Bezirksverein at Kissingen, the Bavarian medical chambers have taken a stand against this unauthorized competition and asked the Bavarian government to use its influence to forbid the carrying on of practice in any form by physicians who are not licensed in Germany

The Robert Koch Tuberculosis Foundation

The Robert Koch foundation for the elimination of tuberculosis which was established five years ago in memory of the discovery of the tubercle bacillus, with a capital fund of 1 250,000 marks ($312,555), has already expended nearly 100 000 marks ($25,000) for promotion of research on tuberculosis At its last session, early in November, an allowance of 3,000 marks was granted for studies on vital staining and tuberculosis, and 1,500 marks for investigations of tubercle bacilli in the blood stream

Expenses of the Prussian Universities

The ordinary expenses for the Prussian universities have increased since 1868 from about 4,000,000 ($1,000,000) to 21,000,000 marks ($5,250,000) in 1911 Corresponding to this, there is also to be noted a marked increase in the number of students The average registry in the Prussian universities has increased from about 7,500 in 1868 69 to about 28,000 students in 1911 12 Hence, the number of students had increased by about 280 per cent, whereas the expenses have increased by 435 per cent In 1868 there were expended for the individual student 536 marks, in 1911, 753 marks About three fourths of the expenses of the universities are covered at present by the government, the remainder coming from the income of the universities, as well as from foundations and other funds

Quiet at Health Resorts

The German committee for hygienic arrangements in health resorts and watering places discussed at its last session the important theme "Quiet at Health Resorts" The following resolutions were adopted for regulating public traffic 1 In the construction of street pavements, noise suppressing reinforcement should be used according to local conditions (Wood, asphalt, macadam, stone pavement is to be avoided as much as possible) 2 Limitation of the street traffic in such a manner as to afford the necessary rest to the guests of health resorts (Prohibition of fast driving of automobiles and other vehicles, prohibition of unnecessary use of horns and whistles and the cracking of whips, limitation of the use of bells and whistles on local railroads and steamship traffic Control of the traffic of freight wagons Practicable limitation of all kinds of noise which disturbs the quiet, with some exceptions which must be approved by the police (such as moving etc) 4 Prohibition of noisy plays of children and of noisy calls by street peddlers 5 Restriction of keeping noisy animals (fowls, cats, dogs, etc) 6 Permission of only the most necessary bell ringing, elimination of the striking apparatus of public clocks 7 Limitation of the construction of buildings to the slack season at the resorts

For the houses the following resolutions were passed 1 The greatest possible deadening of walls and ceilings in the lodging houses 2 The kitchens, water closets, bathrooms, rooms with machinery and rooms for amusement must be arranged so that those living in the house may not be annoyed by the noise produced in such rooms 3 Establishment of certain hours for the beating of rugs, furniture and bedding 4 Restriction of noisy plays of children in the courts, halls and gardens 5 Training the house-servants to perform all their duties with the least possible noise 6 The greatest possible limitation of playing on musical instruments and singing with open windows and in buildings which are not sound proof

Population of the German Empire According to Age

The age relations of the population of Germany, according to the census of 1910, may be summed up in the following table

	Males	Females	Total
Population in 1910	32 040 166	32 885 827	64 925 993
15 years old and under			22 107 930 *
Born before 1851	2 271 366	2 842 838	5 114 204
Aged 15 to 60	18 660 908	19 042 951	†

* 34 1 per cent † 58 per cent

Marriages

Beulah B Richmond M.D, Skelton, W Va, to Miss Florence Josephine Ballard of Long Beach, Cal, November 20

John A Froelich, M D Princeton, Wis, to Miss Emma Williams of Palmyra, Wis, at Milwaukee, November 27

John Charles Norton, M D, Hagerstown, Md, to Miss Ruth Cleveland Atkinson of Baltimore, December 3

Herman H Tuttle, M D, Springfield, Ill, to Miss May L Suddick of Joliet, Ill, at Ottawa, Ill, December 5

Henry Hopson Wilcox, M D, Springfield, Mass, to Miss Emily Jane Wagner of Brooklyn, December 5

George H Scott M.D, U S Army, to Miss Margaret Fleanore Pillow, at Butler, Pa, December 5

Thomas B Kern, M D Allentown, Pa, to Miss Frances Middleton of Philadelphia, November 28

John M Dickson, M D, to Miss Florence L Williamson, both of Cambridge, Mass, recently

Esmond Austin Childs, Geneva, O, to Miss Mary Summers, at Toronto, Ont, November 26

Elmer Lee Cox, M D, Salem, Ia, to Miss Winnifred Childs of Ottumwa, Ia, November 21

C Clayton Koons, M D, to Mrs Grace Roberts, both of Larned, Kan, November 27

Joseph B Unsell, M D, to Miss Willella Stark, both of Louisiana, Mo, December 4

Camden B Eddy, M D, to Miss Mary L Harris both of Louisville, November 28

Calvin Edgar Brown, M D, to Miss Leila Haerther, both of Chicago, December 6

Deaths

Henry Moore, M D Kentucky School of Medicine, Louisville, 1864 a veteran of the Civil War, for many years superintendent of the Midland Railroad Company formerly a member of the board of trustees of the Indiana State School for the Deaf, chairman of the original commission appointed by the Indiana legislature to investigate the practicability of establishing a State Tuberculosis Hospital and later chairman of the board of trustees of the State Tuberculosis Hospital, Rockville, Ind state organizer of the National Red Cross Antituberculosis Campaign, died in his office in the State House, Indianapolis December 2, from cerebral hemorrhage, aged 72

George Clinton Crandall, M.D University of Michigan, Ann Arbor 1890, a member of the American Medical Association professor of medicine in the St Louis University, formerly a member of the medical staff of the Northwestern Michigan State Hospital Traverse City Mich president of the consulting staff of the St Louis City Hospital, consulting physician to St Ann's Lying In Hospital, and medical director of the St Louis Society for the Prevention and Relief of Tuberculosis died at his home in St Louis, December 5, from nephritis, aged 47

Rem Lefferts Disbrow, M D College of Physicians and Surgeons, New York City, 1862 a member of the Medical Society of New Jersey, first president of Ocean County Medical Society, surgeon of the Fourteenth New York Volunteer Infantry during the Civil War, for several years a president and director of local banking and trust companies a member of the board of freeholders and county board of election, died at his home in Tom's River, November 11, from senile debility, aged 77

Nathan Gideon Ward, M D Jefferson Medical College, 1893, a member of the American Medical Association, president of the Philadelphia Chemical Association, clinical professor of laryngology and rhinology in Temple University, Philadelphia, aurist and laryngologist to St Agnes Hospital ophthalmologist to Charity Hospital and also a member of the staff of the Samaritan and Garretson hospitals Philadelphia, died at the home of his parents in Elizabeth City, N C, December 3 aged 47

William B Crum, M D Howard University, Washington, D C, 1880 a prominent colored practitioner of Charleston, S C once surgeon in the National Guard of the state and visiting physician to the Charleston Negro Hospital, appointed collector of the Port of Charleston in 1902, and minister resident to Liberia and consul general at Monrovia in 1909 died in Charleston, December 7, from fever contracted at his post of duty in West Africa, aged 53

Ellsworth Eliot, M D College of Physicians and Surgeons New York City, 1852, trustee and registrar of his alma mater for several years, a member of the American Medical Association and New York Academy of Medicine, and president of the Medical Society of the County of New York in 1872, also president of the Society for the Relief of Widows and Orphans of Medical Men died at his home in New York City December 9, from bronchitis, aged 85

Elizabeth Simpson Mitchell, M D Queens University Kingston, Ont, 1888 L R C S, L R C P Edinburgh, L F P S Glasgow, L S A London, 1888, the first woman to receive a license to practice in the Province of Quebec a practitioner of Montreal until 1909 when she moved to Bournemouth England died in Nashua, N H, November 30 aged 48

Cornelius P Meredith, M D Pulte Medical College, Cincinnati, 1881, of Louisville, Ky, formerly president of the Southwestern Homeopathic Medical College and at one time a member of the Kentucky State Board of Health, a Confederate veteran, died in the home of his son in Louisville December 2, from uremia, aged 73

Charles Henry Thompson, M.D College of Physicians and Surgeons New York City, 1868 a member of the Medical Society of New Jersey mayor of Belmar, N J, from 1891 to 1893, for two terms a member of the borough commission of Ocean Beach, died at his home in Belmar, December 3 from disease of the intestines, aged 69

Henry Sayre [illegible] York University, New York City 1861, a me[illegible] [illegible]ican Medical [illegible]tion
of Los Angeles, [illegible]
cine in the Uni[illegible]
titioner of Los [illegible]
ber 29, aged [illegible]

George Edwin Jones, M D Medical College of Ohio, Cincinnati, 1859, a member of the American Medical Association, formerly of Evansville, Ind , acting assistant surgeon, U S Navy, during the Civil War, died at his winter home in St Augustine, Fla , November 29, from cerebral hemorrhage, aged 77

John Young, M.D University of Michigan, Ann Arbor, 1874, a member of the American Medical Association, a pioneer practitioner of Presque Isle County, Michigan, and for more than twenty years chairman of the county board of supervisors, died at his home in Onaway, December 3, from heart disease, aged 66

Albert E Johnson, M D George Washington University, Washington, D C , 1869, formerly a member of the American Medical Association, a member of the Medical Society of the District of Columbia, at one time city physician of Washington, died at his home in that city, about November 5, aged 72

John Rogers Merrill, M.D College of Physicians and Surgeons, New York City, 1886, a member of the Medical Society of New Jersey, a practitioner of Paterson, N J , until October last, when he moved to Pasadena, Cal , on account of his health, died at his home in that place, December 1, aged 51

Charles Emory Rogers, M.D Bellevue Hospital Medical College, 1880, a member of the American Medical Association, local surgeon of the Milwaukee System at Montevideo, Minn , and founder of the Montevideo Hospital, died suddenly at his home, December 3, from angina pectoris, aged 62

Edgar D York (license, Kansas, years of practice, 1901), a practitioner of Rawlins County since 1881, representative in the legislature in 1887 1888 and 1891 1892, a veteran of the Civil War, first mayor of Atwood, Kan , died in the State Hospital, Ingleside, Neb , November 5, aged 75

Lee C George, M D Tulane University, New Orleans, 1896, of Monroe, La , a member of the American Medical Association, local surgeon for the Queen and Crescent System, died in the Gulf Coast Health Resort, Biloxi, Miss , December 3, from nephritis, aged 43

John Richardson Hoffman, M.D Jefferson Medical College, 1868, a member of the Medical Association of the State of Alabama, surgeon in the Confederate service throughout the Civil War, died at his home near Athens, December 3, from senile debility, aged 82

Isaac N Cohen, M D Friedrich Wilhelm University, Berlin, Germany, 1872 a surgeon in the German Army until 1890, of La Crosse Wis , died in the La Crosse Hospital, December 1, from acute peritonitis, for which operation was performed without avail aged 62

Arthur MacCabe, M.D Baltimore University, 1897, Queens University, Kingston, Ont , 1903, a member of the American Medical Association, formerly chairman of the Board of Health of Gloucester, Mass , died at his home in that city, November 12, aged 45

William J Kennedy, M.D Minnesota College of Physicians and Surgeons, Minneapolis 1903, formerly local surgeon at Enderlin N Dak , for the Minneapolis, St Paul and Sault Ste Marie Railway, died at his home in Olga, N Dak , recently, aged 35

Daniel Stanislaus Harkins, M.D Harvard Medical School, 1888 a member of the Massachusetts Medical Society, for two terms a member of the Boston School Board and quarantine physician, died at his home in Boston, December 8, aged 48

Harry C Guillot, M.D Detroit College of Medicine, 1891 for five terms mayor of Pontiac, Mich formerly a member of the staff of Eastern Michigan State Hospital in that city, died at his home December 3, from valvular heart disease, aged 45

Simon S Wilcox (license, years of practice, Illinois, 1877), a veteran of the Civil War for half a century a practitioner of Hutton Township, Vermilion County, died in the Soldiers' Home Danville, Ill , November 27, from senile debility, aged 87

William D Humphrey, M D Northwestern University Medical School, Chicago, 1899 of Virginia, Ill , who was injured five weeks ago in a runaway accident, sustaining a fracture of the skull, died in a hospital in Jacksonville, December 5, aged 48

Robert A. Gunn, M.D University of Buffalo N Y., 1866, of New York City, died in Bellevue Hospital, December 7, from the effects of morphin, aged 68

William K. Flatt, M.D Hahnemann Medical College, Chicago, 1869 died at his home in St. Paul, Minn , December 5, from cerebral hemorrhage, aged 82.

Francis Duffy, M.D University of Virginia, Charlottesville, 1868, College of Physicians and Surgeons, New York City, 1875, a member of the Medical Society of the State of North Carolina, died at his home in Newbern, N C , November 5

J Hartridge Kennedy, M D Medical College of Georgia, Augusta, 1892, was found dead at his home in Lew, Ga , December 2, from the effects of chloroform, believed to have been self administered, with suicidal intent, aged about 43

John Thomas Jennings, M D University of Louisville, Ky , 1891, died at his home in Ramona, Okla , November 29, from the effects of a gunshot wound of the head, self inflicted, it is believed, with suicidal intent, while despondent, aged 40

Benjamin F Hamell, M D University of Pennsylvania, Philadelphia, 1863, of Oakland, Cal , was found dead in his sleeping car berth on an eastbound Southern Pacific train at Ogden, Utah, December 2, from heart disease, aged about 70

William H Haynes, M D Medical College of Ohio, Cincinnati, 1889, of Aurora, Ind , a member of the Indiana State Medical Association died at the home of his sister in Wilmington, Ind December 4, from pneumonia, aged 53

Alexander Bailey, M.D University of Louisville, Ky , 1881, for several years superintendent of the State Feeble Minded Institute, Frankfort, Ky , died at his home near Frankfort, November 24, from pneumonia, aged 62

Albert P Harrison, M.D College of Physicians and Surgeons, Kansas City, Kan , 1902, of Coldwater, Kan , a member of the Kansas Medical Society, died in the Wichita Hospital, November 21, from heart disease, aged 39

Henry Gastineau, M D Central College of Physicians and Surgeons, Indianapolis, 1895, of Howesville, Ind , at one time treasurer of Greene County, died at the home of his son in Howesville, December 3, aged 68

Joseph McCann, M.D Starling Medical College, Columbus, Ohio, 1854, died at his home in Delaware, Ohio, December 1, from cerebral hemorrhage, following a fall from a ladder, eleven days before, aged 88

Edward F Schwedler, M.D University of Leipzig, Germany, 1848, for many years a member of the visiting staff of the German Hospital, New York City, died at his home, December 7, from pneumonia, aged 90

Samuel J Tilden Ritter, M.D Eclectic Medical Institute, Cincinnati, 1897, a director of the Bethlehem (Pa) Trust Company, died at his home in Bethlehem, December 4, from pneumonia, aged 36

William M Cooley, M.D Hahnemann Medical College, Chicago, 1868 a pioneer practitioner and clergyman of Dickinson County, Kan , died at his home in Herington, December 3, aged about 78

William P Townsend (license, Texas, Fifth Judicial District Board 1891), a member of the State Medical Association of Texas was found dead in a well at his home in Mattinburg December 2

Monroe L Vansant, M.D Hahnemann Medical College, Philadelphia, 1857 a physician and dentist of Philadelphia died at his home, September 22, from senile debility, aged 90

David Alexander Kittle, M D, Washington University, St Louis, 1853, since 1865 a practitioner of Kansas City, Mo , died at his home, December 1, from senile debility, aged 92

Charles Billon Gratiot, M D Missouri Medical College, St Louis, 1849, one of the oldest practitioners of St Louis, died at his home, December 11, from senile debility, aged 84

Lemuel S Lawson, M D University of Maryland, Baltimore, 1867 for forty three years a practitioner of Dallastown, Pa , died at his home, December 5, from uremia, aged 75

Andrew James Boman, (license, Michigan, years of practice 1900) for nearly thirty years a practitioner of Alpena, died at his home in that city, November 30, aged 76

Russell H. Sparks, M D Medical College of Ohio, Cincinnati, 1871 of Stamping Ground, Ky , died recently at the home of his sister in Pleasureville, aged 80

William E Moon, M.D Keokuk (Iowa) Medical College 1892, died at his home in Traverse City, Mich , December 9, from carcinoma of the stomach, aged 49

William Minser, M.D Cincinnati College of Medicine and Surgery, 1882 formerly of Versailles, Ohio, died suddenly in Greenville, Ohio, December 1, aged 52

George Mays (license, Texas, 1907) a practitioner of Houston since 1869, died at the home of his daughter in that city December 2, aged 65

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

ADVANCED MEDICAL SCIENCE INSTITUTE, A NOTORIOUS QUACK CONCERN, RUN OUT OF KENTUCKY

About Sept 20 1912, a quack concern styling itself variously the "Advanced Medical Science Institute," "Radio Electric Company," "Witman Medical Company" and "Delish Etts Manufacturing Company," with an alleged capital stock for each of these concerns of from $25,000 to $2,000,000 and claiming to be a part of the State Land Company of Oklahoma, with branches in a dozen or more states, began operations in one of the principal office buildings in Louisville Flaming advertisements in the newspapers announced that it had expert diagnosticians and scientific apparatus too costly and accurate for the medical profession to possess or appreciate, and in a few days reported cures so numerous and miraculous as to attract a large clientele The State Board of Health put the machinery of the law in operation and its special agents, male and female, reported in a few days that X. W Witman, the head of the concern and its expert diagnostician, was not a physician, and that the only medical man in it was one who had failed as a practitioner and was employed in an attempt to legalize its practice at a salary of $15 a week The scientific apparatus—a fake worthy of the operators—consisted of a cheap fluoroscope Witman pretending to look through the body into a blind box, would declare that he saw handfuls of gall stones, and stomach, lung and kidney lesions, and thus found it easy to relieve the unfortunates of any surplus cash they had or could obtain

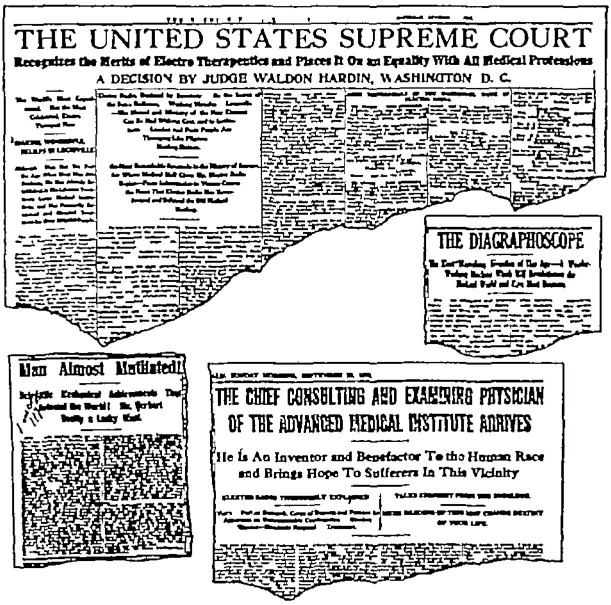
Twenty indictments were secured at the next sitting of the grand jury (most of them not for violations of the medical law, it should be observed) and warrants were taken out from day to day as evidence could be secured One woman, it is alleged, furnished $3,000 to finance the concern and its defense, able attorneys were employed by it, a virulent crusade was begun in the press against the State Board of Health, the State Medical Association and the American Medical Association, and women were employed in broad and systematic efforts to blackmail and intimidate leading members of the profession, especially those connected with the prosecution or summoned as witnesses All of this was of no avail The attorney of the board, to whom chief credit is due for the freedom of Kentucky from open quackery for the last twenty years, had prepared the cases with such care and ability that the woman in the concern who had been used in the efforts to discredit members of the profession, turned state's evidence

ADMIT GUILT

Nine of the indictments were against the Delish Etts Manufacturing Company, Dr George W Foreman, X. W Witman, W M Foreman and Frances Holst for failure to file a certificate One was against the Advanced Medical Science Institute and the persons named for unlawfully practicing medicine, and nine against the same institute and persons for failing to file a certificate The failure to file a certificate refers to the engaging in business under an assumed name as in the cases of the Delish Etts Manufacturing Company and the Advanced Medical Science Institute, without having filed a certificate giving the names, places and residences of all persons actually interested in and conducting the business, and the nature of the business There were eighteen counts of this sort The other two were for practicing medicine illegally On the eighteen charges, by agreement, Witman was fined $25 each and $50 each on the two latter, making, together with costs, nearly $700, which Witman paid Dr Foreman pleaded guilty to one charge of doing business under an assumed name, the Advanced Medical Science Institute, and a fine of $50 was imposed, which is included in the above sum Frances Holst filed a statement in court as to her connection with the business and agreed to cease having any future connection with such business The cases against her and W M Forman were dismissed Witman admitted that the business had been illegally conducted, that the offices would be immediately closed and that he would not in future engage in similar business in the state of Kentucky This is all a matter of record in the criminal courts of that state The concern closed its offices within an hour and notices were at once issued for Dr George W Foreman to appear before the State Board of Health at its next meeting to show cause why his certificate to practice medicine should not be revoked "for gross unprofessional and dishonorable conduct of a character likely to deceive and defraud the public" Foreman graduated from the Kentucky School of Medicine in 1902, his name being given as George Forman He was licensed in Kentucky in 1903 under the name of George W Foreman

NEWSPAPER RESPONSIBILITY

This, for the time being at least, ends the career of one of the crudest and most brazen examples of advertising quackery



THE UNITED STATES SUPREME COURT

Recognizes the Merits of Electro Therapeutics and Places It On an Equality With All Medical Professions

A DECISION BY JUDGE WALDON HARDIN, WASHINGTON D. C.

THE DIAGRAPHOSCOPE

Man Almost Mutilated!

THE CHIEF CONSULTING AND EXAMINING PHYSICIAN OF THE ADVANCED MEDICAL INSTITUTE ARRIVES

He Is An Inventor and Benefactor To the Human Race and Brings Hope To Sufferers In This Vicinity

Photographic reproduction (much reduced) of portions of some of the advertisements put out by the Advanced Medical Science Institute fraud

which the daily papers of Louisville aided and abetted by printing large reading notice advertisements with flaming headlines It is a matter of astonishment that in this day and age reputable newspapers should lend themselves to such gross forms of swindling In effect they make themselves partners in a crude confidence game in which their own patrons are not only swindled out of their money but are doubtless, many of them, irreparably harmed by the treatment, or by the lack of the proper treatment they require Many of the statements made in these advertisements are so extravagant and absurd as to be laughable and really should not deceive any layman of average intelligence Yet these quacks must have done a large business in Louisville, else they could not have paid for the extensive advertising space purchased by them in these newspapers

A few examples of statements from these advertisements are given below

The following appeared in the Louisville *Times* October 17

MAN ALMOST MUTILATED! SCIENTIFIC MECHANICAL ACHIEVEMENTS THAT ASTOUND THE WORLD! MR HERBERT BEATTY A LUCKY MAN!

After an automobile accident which all but killed him outright Mr Herbert Beatty s life was by means which has astounded the civilized world The following is what was done for Mr Beatty at the Advanced Medical Science Institution 708 Realty Building A glass eye an artificial nose a silver plate in his skull and a false lining in his stomach was inserted, and yet Mr Beatty lives and enjoys perfect health In answer to the question when interviewed by a reporter the doctor explained Almost anything can be done nowadays by electricity when in the hands of a scientist The lining of Mr Beatty s stomach was deposited there by a powerful current which is perfectly harmless and painless bismuth is used as that metal can be removed after a cure is effected as readily as when placed there by simply reversing the polarity of the current. When this lining is placed in a diseased stomach or bladder it coats the diseased mucous lining protecting the diseased parts from the matter which would constantly irritate the parts and prevent a cure without this protection This great discovery is a boon to those sufferers from stomach trouble and intestinal canal or any irritation of the kidneys caused by stricture or ulceration of any kind The multiple machine the only one in the U S of America was applied and one application dissolved that troublesome malady in less than three minutes time '

Equally interesting with the "multiple machine," described above, which cured a "stricture or ulceration" in three minutes, is the "Diagraphoscope" which is stated in the Louisville *Herald* of September 20 to be "The Most Marvelous Invention of This Age—A Wonder Working Machine Which Will Revolutionize the Medical World and Cure Most Diseases" In the absurd description of the "diagraphoscope" which is called 'the eighth wonder of the world," it is said that it is

> Doing more for diseases than an ocean of drugs or a forest of surgeons knives It gives a diagnosis that is absolutely true—not guess work This is accomplished by showing to the naked eye every organ in the patient s body By means of this phenomenal machine s powers one can see the heart in action the rise and fall of the diaphragm a spoonful of bismuth passing down the throat Any constriction is as visible as the light of day as are kidney stones or in fact any abnormal condition It will show gall stones so often believed to be cirrhosis of the liver You can see right past the appendix, often observing the kidney stones so often mistaken for appendicitis Any enlargement of the joints is immediately revealed and taking it all in all makes the formerly much vaunted *x*-ray look like a toy

In another reading notice in the Sunday *Herald* of Sept 22, 1912, it is announced in great headlines that the chief consulting and examining physician of the Advanced Medical Institute has arrived He is described as the "great scientist who has revolutionized the medical profession and startled science" with his electro radio The important announcement is made that he had brought his auto and had engaged beautiful apartments in the fashionable part of town But the most wonderful part of this advertisement is the description of the way in which they examine the patient in the Advanced Medical Science Institute It is as follows

> "The first thing we do with a patient who insists he has heart trouble is to take a drop of blood from his finger My celebrated bacteriologist examines that blood with his microscope which magnifies 4 000 times and separates every blood-corpuscle the red from the white We measure them count them watch the activity in life the color of them and their shape We then place the instrument imported from London under the patient s arm It tests the blood pressure through the heart The urine is analyzed by electricity The heart is looked at It can be seen pulsating as plainly as looking through an open window We look through the body to see if there are any abnormal conditions. That tells the story In nine cases out of ten we find the patient suffering from an effect and not the supposed cause"

The brazen assurance of these quacks is illustrated still further in an advertisement in one of the Louisville daily papers in which is quoted almost completely an article by a prominent surgeon in one of the popular magazines concerning medical ethics The surgeon's name is signed to the article and the article is used in an attempt to show why regular physicians are not worthy of confidence and that faith should be placed in the electro radio treatment of these quacks

MORE LYING

A still more flagrant example of the sheer nerve of these swindlers is found in a half page advertisement in the Louisville *Evening Post* Oct 12, 1912, in which it is said in headlines extending across the whole page that 'The United States Supreme Court Recognizes the Merits of Electrotherapeutics and Places It On an Equality with All Medical Professions A Decision by Judge Waldon Hardin, Washington, D C" Then it pretends to quote from and comment on the Collins decision by the United States Supreme Court It quotes Judge Hardin as having delivered himself of the following brilliantly expressed thought presumably from the Collins case "The allopathic doctors dug their own pits in the Collins case They never realized they had hold of a live wire until it was too late"

There is no Judge Waldon Hardin on the bench of the United States Supreme Court or in the district courts The Collins case was a case from Texas involving the reregistration of an osteopath who had a license under a previous medical act, and had nothing to do with electrotherapeutics The decision of the Supreme Court in that case sustained the new Texas law requiring the osteopath to register anew This serves only to illustrate the brazen effrontery of this quack concern which swindled the people of Louisville and vicinity probably out of many thousands of dollars in a few months The fine of about $700 amounted really only to a cheap license fee for these swindlers and they can afford to go somewhere else and do the same thing, which they probably will While the people of Louisville are to be congratulated on having been saved from further exploitation by this bald form of quackery through the activity of the profession and the state board of health when they once got in action, yet they have no reason to feel proud of their neighbors and friends, the proprietors of the newspapers who published the advertisements of these fake concerns and thus made possible their swindling operations

---

Correspondence

Failure of Christian Scientists to Differentiate Dropsy and Pregnancy

To the Editor —Apropos of the wonderful cure (?) of Mabel Hite by the Christian Scientists as reported in The Journal (Nov 23, 1912, p 1896), I think that the report of a case in which I was called last month will be of interest I was engaged by a man to attend his wife during her confinement, which was expected to occur in a few weeks He said that they were Christian Scientists and gave me to understand that I would be called when labor began In answer to my questions, he stated that his wife was feeling well and that all of the functions were normal In due time I was hurriedly called, as the woman was said to be in labor When I arrived at the house I was greatly shocked to find the patient sitting up but in a dying condition On each side was a sister "healer" assuring her that she was just nervous, when in fact she was almost pulseless, lips blue, cold to knees and elbows and gasping for breath

As soon as I saw the conditions I had counsel called We found that the patient was not pregnant, but had general dropsy She died within two hours A post mortem was refused, so we are unable to say what caused the dropsy Oh, Religion, what fearful things are done in thy name!

B N Stevens, M D, Chillicothe, Mo

Danger of Infection from the Cigar Clipper

To the Editor —An incident which recently occurred forcibly called to mind the danger from the use of certain public articles, in this case the cigar clipper I was standing in a restaurant talking to a friend when a man came in who, as I knew, was afflicted with syphilis of rather recent inoculation He had mucous patches in his mouth at the time He bought a cigar and put it in his mouth He then remembered that he had forgotten to clip the end of the cigar, so he took the cigar from his mouth and clipped it in the clipper standing near The next man after him might easily contract the disease It is needless to say that I have never since cut off the end of a cigar in a public cigar clipper

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed Every letter must contain the writer's name and address but these will be omitted on request

PROTECTION OF OTHER MEMBERS OF THE FAMILY FROM INFECTIOUS COLDS

To the Editor —I am interested in the problem of protecting other members of the family in cases of influenza and infectious colds It is often impossible to isolate the patient. I am having fairly good success with partial isolation together with gargles formaldehyd and eucalyptus inhalation etc I think it would be of interest not only to me but to many others who have the same problem if you would outline the best methods of protecting the well from the infection E P

ANSWER.—The problem of protecting persons against infectious colds is quite similar to that of protecting them against the other infectious diseases Isolation is a measure of chief importance It is very doubtful if the infections which give rise to the symptoms of a cold are spread to any extent by means of fomites The infecting agent appears to be the living patient, frequently a convalescent one, who still throws out from the mouth a fine spray laden with infectious germs This is more particularly the case in loud speaking, in which it has been shown that such germs can be carried to a distance of several feet When complete isolation is impracticable the patient can limit his infectiveness by the use of some form of sputum receiver and by special care not to soil with nasal or oral secretions his own hands or clothing, and not to come too close to other persons His dishes, table napkins and handkerchiefs might well be kept carefully separate so that no one else will use or handle them until time to wash them One need have little fear of the infectious matter that might possibly persist through a thorough washing, but boiling would be a sure disinfectant

Ordinary cleanliness on the part of the other members of the household, especially frequent washing of hands, will probably be a sufficient means of protection in place of any extensive means of disinfection An important measure in preventing the reception of such germs is to secure the healthy condition of the mucous membrane of the nose and pharynx The fact should be remembered that the nasal mucous membrane is affected by conditions in other organs, particularly the skin the digestive organs and the sexual apparatus The local treatment of the nasopharynx with antiseptics is probably of slight value, except when there is present some viscid secretion to be removed Too extensive spraying of the throat may even be prejudicial by removing a layer of protecting mucus and *leaving the mucous membrane perhaps more accessible to the* invasion of pathogenic germs

BLOOD TRANSFUSION—SALINE SOLUTION—ALYPIN—ARISTOL—BOVININE

To the Editor —1 What is the simplest practical method of determining whether a donor is suitable for blood transfusion? 2 What strength saline solution would you recommend for intravenous administration? 3 What is Alypin? What is its therapeutic value? 4 What is Aristol? 5 What is Bovinine? M Y D

ANSWER —1 The donor should be free from disease If sufficient time is allowable it would be well to perform the Wassermann test. It is preferable that the donor should be a blood relative, as the blood of strangers is sometimes hemolyzed by the blood of the recipient It might be well to determine beforehand whether the blood of the recipient exercises a hemolytic action on the blood of the proposed donor

2 Sodium chlorid, 0 9 per cent., gives a solution which is isotonic with the blood plasma and hyperosmotic in sodium chlorid A better solution would be one containing 0 6 per cent sodium chlorid and 0 3 per cent other salts, especially sodium bicarbonate A solution containing 0 7 per cent sodium chlorid is usually near enough to the molecular concentration of the blood plasma for ordinary use

3 See New and Nonofficial Remedies, 1912, p 27

4 Aristol is a trade name for thymol iodid See New and Nonofficial Remedies, 1912, p 243

5 Bovinine is a nostrum claimed to be a preparation from beef blood. It was investigated by the Council on Pharmacy and Chemistry and the results were published in THE JOURNAL, Nov 20, 1909, p 1756 The report has also been published in the "Reports of the Council on Pharmacy and Chemistry" for 1909, pp 137 and 142 and in the 'Propaganda for Reform in Proprietary Medicines," p 28. Bovinine was rejected by the Council

NEOSALVARSAN IN RHEUMATISM AND ANEMIA

To the Editor —Please advise me with reference to the use of neosalvarsan in the treatment of rheumatism and anemia
JAMES ROSS M D., Moline Ill

ANSWER —Salvarsan has been used with apparently good results in some cases of pernicious anemia A similar use of neosalvarsan is reasonable, but we do not know that it has been applied in this way

DENTAL ANESTHETICS

To the Editor —What is most effective to prevent pain in the extraction of teeth? S T

ANSWER —The sensibility of the gums can be reduced by rubbing them with a solution of cocain or one of the many proprietary cocain substitutes, so that the prick of the hypodermic needle will not give pain In some cases a merely psychic influence may be sufficient to secure an almost painless extraction Rubbing a remedy on the gums might secure this psychic effect in a considerable number of cases

Local anesthetics and obtundents are agents to produce insensibility to pain in a circumscribed area of tissue They are used to act at once on nerve endings in a given locality especially in the extraction of teeth Local anesthetics are divided into (A) soluble local anesthetics, (B) insoluble local anesthetics and (C) refrigerant local anesthetics

A The best known soluble local anesthetic is cocain hydrochlorid According to Preyer's conception, local anesthesia is produced as follows Cocain possesses a distinct affinity for the living protoplasm of the nerve cell, it enters with it into a labile union, thus producing local anesthesia, which lasts until its temporary union is broken up by releasing the chemical—not as the original cocain, however, but as *an inert compound of a simpler structure* In other words, the living tissues rid themselves of the poison in some unknown manner

Some of the formulas for local anesthetic solutions of cocain are

℞	gm or c.c.			
Cocainae hydrochloridi		32		gr v
Sodii chloridi		25	or	gr iv
Aquae destillatae	30			fl ℥j

M Sig Cocain injection for dental purposes To each cubic centimeter add 1 drop of epinephrin solution when used (Prinz)

Following are two formulas for local obtundents

℞	gm or c c.		
Cocainae hydrochloridi	1		gr xv
Phenolis liquefacti	4	or	ʒj

M Sig Apply the heated solution to hypersensitive dentin (Jenkins)

℞.	gm or c c.			
Cocain (alkaloid)	1	3		gr xx
Chloroform	8		or	fl ʒij
Ether	30			fl ℥j

M Sig Apply to the cavity on a small pledget of cotton and evaporate to dryness (Buckley)

Novocain is one of several cocain substitutes (see New and Nonofficial Remedies, 1912, p 152) It is said to have the same action on the peripheral nerves as cocain, with an equal amount of anesthetic potency Applied locally, it has no side or after effects, and is non irritating to the soft tissues A formula commonly used is

℞	gm or c.c			
Novocain		6		gr x
Sodii chloridi		25	or	gr iv
Aquae destillatae	30			fl ℥j

M Sig To each cubic centimeter add 1 drop of epinephrin solution when used (Prinz)

B Among insoluble local anesthetics are comprised a number of *synthetic compounds introduced within recent* years which possess marked analgesic power when applied in substance on painful mucous membranes or abraded surfaces Anesthesin, Orthoform New and Propaesin are illustrations The following anesthetic mixtures may be used

℞		gm		
Anesthesin				
Corn starch	āā	4	or	āā ʒj

M Sig Dusting pow

℞	gm		
Orthoform		or	ʒj
Lanolin			℥j

M f unguent

C Refrigerant local anesthetics are local applications which abstract blood from the tissues They lower the temperature, diminish sensation, and reduce the volume of the parts to which they are applied When continuously applied in due time they produce definite anesthesia These freezing agents are restricted to small areas especially around the roots or root of the tooth to be removed. Ether and ethyl chlorid are used for this purpose

LITERATURE ON INDURATIVE HEADACHE

To the Editor —Please give me the literature on indurative headache (*musculäre Kopfschmerz* or *cephalée musculaire*)

A M., ——— Texas

ANSWER —Following are some of the articles on the subject

ORYZANIN

To the Editor —Somewhere recently I saw an article referring to an article by a Japanese investigator on the active principle in rice polishings which he had named Oryzanin I thought it was in an editorial in THE JOURNAL but cannot find it Please refer me to the article if you did publish it and also to the original article

W L. BEECHER M D Chicago

ANSWER —The editorial was published in THE JOURNAL, Sept 14, 1912, page 883 The original article, Ueber Oryzanin, ein Bestandtheil der Reiskleie und seine physiologische Bedeutung, was published by V Suzuki, T Shimamura and S Odake, in the *Biochemische Zeitschrift*, 1912, xliii, 89

A REQUEST FOR MATERIAL ON LEUKOCYTIC INCLUSIONS IN SCARLATINAL BLOOD

To the Editor —In order to arrive at a definite conclusion as soon as possible regarding the diagnostic value of the leukocytic inclusions which have been described in the blood of scarlatinal cases I would deem it a personal favor if physicians having such patients would send me a few blood smears on slides or cover glasses from every case observed within the next few months together with a note stating the day of the disease the existence of eruption run of temperature and apparent severity of the case

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF POST GRADUATE WORK CONTRACT PRACTICE, LEGISLATION, MEDICAL DEFENSE AND OTHER MEDICOLEGAL AND ECONOMIC QUESTIONS OF INTEREST TO PHYSICIANS

A NATIONAL DEPARTMENT OF HEALTH

Last week we commented on the interest which is being taken by the lay press with reference to the national Department of Health and the changed views in regard to it Another evidence is an article by Dr John A. Wyeth of New York entitled "Why a National Department of Health is Needed," which appeared in the Sunday edition of a group of daily newspapers Following are a few paragraphs from Dr Wyeth's article

"There is, in the President's cabinet, a Secretary of Agriculture, one of whose duties is to look after the welfare of our domestic animals, but there is no voice in the cabinet to speak out for the welfare of the women and children—and surely no one will gainsay that these are more valuable than our hogs, horses and cows

"I am not in favor of the Owen bill, for the reason that it is a compromise The Department of Health should not be a secondary bureau in any other department—nothing but a special department with a Secretary of Health, as a member of the cabinet, should be accepted by the American people and by that powerful organization, the American Medical Association, which, representing 130,000 busy practitioners of medicine in the United States, is working earnestly and effectively in the campaign of education to accomplish this end.

'The question of states' rights is not involved—without interference in any way with the prerogatives of the various state boards, these can be employed in successful cooperation for the general welfare No single state, or group of states, should be made to bear alone the expense of fighting an epidemic—it is not fair to the state, or to its neighbors who are threatened Epidemics do not respect interstate boundary lines, and a stream vilely polluted in one community may flow on and on through a dozen other states, carrying its poison to the helpless people who are compelled to use its waters

"The world was never more under obligations to the self sacrificing work of the medical profession than now Its members are giving not only their time and energy and means, but their lives in this warfare against disease and death The young, the brilliant Ricketts, who discovered the cause and the cure of that fatal endemic, the 'Rocky Mountain fever,' died in Mexico while studying the cause of typhus, himself a victim to this malady Lazear and Carroll laid down their lives after being bitten by yellow fever mosquitoes in testing their then theory—now no longer a theory but a fact, which their death proved—that this dread epidemic disease was carried from man to man by this insect With the knowledge thus gained, Dr Gorgas banished yellow fever from Havana after a century of its presence there Think of what all this means to life, happiness and to commercial prosperity!

Turn to another fatal disease, typhoid fever It is no longer dreaded In the Spanish American war our men died like sheep with 'the rot' Twelve years later an equal number of troops, subjected to the identical conditions of climate and location and time in camp, did not lose a single life, as compared to the thousands that died and were ill in 1898 and 1899 in Florida and at the Chickamauga camp Medical science had won another great victory and typhoid fever was ranked with the preventable diseases

'I could extend this list for many columns, but these should suffice to show what progress has been made and is being made, and what can be done to save life and assure health and happiness, provided always that proper authority and power are given to enforce obedience to the requisitions of scientific sanitation Colonel Gorgas could never have driven yellow fever from Havana without the discipline and power which General Wood lent him He failed at Panama at first, because red tape hampered him No sooner had these restrictions been removed in answer to the powerful protest of the American Medical Association than the death rate began to go down and down until within a year the Canal Zone was fever free and had become the white man's home

What is true of yellow fever and typhoid fever and malarial disease is true of tuberculosis and all the other wide spread diseases. It is up to the American people to secure the maximum of health and usefulness for themselves by cooperating with the medical profession in its humane work It can best be done by a national Department of Health and a Secretary of Health in the President s cabinet "

A RELIGIOUS JOURNAL ON PUBLIC HEALTH

An interesting editorial comment, as showing the growing interest of religious publications in health matters, appears in a recent issue of the *Congregationalist* Under the heading of 'The Public and the Doctors," the editor says

"The private and individual activity of public spirited physicians in matters of the common weal has always been a source of strength to the community But the time has come, we think, for a more corporate activity and sense of duty Take the marriage question, for example The public would pay far more attention to the voice of associated doctors and surgeons than they do the words of the clergy Some of our advanced ministers are claiming the assistance of physicians in determining whether they have a right to bind men and women together in wedded life It would be well if the physicians could meet this demand by formulating a basis for certificates of fitness for marriage resting on something more than the individual doctor's opinion

"There are great reforms that bear directly on the prevention of disease and the lowering of the health standard in certain trades and employment of the physically unfit The question of vocational poisonings, such as the lead poisoning of the painters' and potters' trades and the phosphorus poisoning of the match trade, is one in which we need the voice of that profession which deals with health We have a right to claim its corporate leadership toward reform The lowering of the stamina of the race by child labor, by overwork in bad surroundings and the employment of women in unfit trades—are not these matters which concern a medical congress as intimately as the grafting of bone on bone, the replacement of tissue and the clean and healing use of the knife?

"In a word, we hope for the time when the preventive and prophetic work of the medical profession will be at least as large as its effort for recovering lost ground of health If the doctors will safeguard our health and keep us from illness as individuals and as a people, we can afford to subsidize them From the point of view of their own pride and satisfaction, we think it would be better to keep people well rather than to cure them Perhaps, when they have perfected their organization for the public responsibilities that offer, they will petition us to pay them on the Chinese plan of a salary so long as we are well, and a ceasing of pay while we are ill and they are working at our cure "

PHILADELPHIA COUNTY MEDICAL SOCIETY

Meeting held Oct 23 1912

The President, DR L JAY HAMMOND, in the Chair

Occurrence of Bence-Jones Protein in Conditions Other Than Those of Characteristic Myeloma

DRS C G GUTHRIE and THOMAS R BOGGS, Baltimore Although the great majority of cases of multiple myeloma show Bence Jones proteinuria, carefully studied instances of the disease have been reported without the excretion of this unusual body in the urine In others it has been absent either early or late in the disease Clearly established Bence Jones proteinuria has occurred in diseases other than multiple myeloma, among others, leukemia, injury, and in one case of metastatic carcinoma of the bones In our case the original tumor was in the breast with wide spread metastatic involvement of the bony skeleton The condition was diagnosed clinically *intra vitam* and confirmed by the examination of a portion of the femur after death The Bence Jones protein was present in the urine during the period of examination, and its identity was clearly established by chemical tests From this observation and from a study of the literature, we conclude that Bence Jones proteinuria bears neither a constant nor a specific relation to myelomatosis, but may be associated with any one of a variety of disease processes involving the bone marrow

DISCUSSION

DR ALEXANDER RANDALL That the mere calling of attention to this matter in Baltimore brought to notice four cases in a year is suggestive that all cases of obscure bone marrow disease, anemia and leukemia should be examined for this body From Dr Boggs' deductions I think we can say that with the finding of this body in the urine we have a case of bone marrow disease The substance has been found in a variety of conditions and in many parts of the body, and it is to be regarded as an entity I should like to ask Dr Boggs whether the bone marrow has any characteristic appearance When we realize that the kidneys have to do with all the metabolic processes of the body, and when we have a test that will tell us the function of the kidney, we shall have a wide sphere of activity in working out these processes

DR. JAMES M ANDERS It is an interesting fact that, following the discovery of this protein body in the urine by Bence Jones in 1847, the subject received scanty attention for twenty two years Other observations were reported in 1864 and in 1870. In 1902, Dr Napoleon Boston and I reported three cases, and at that time made a review of the literature A number of cases were found coming under the head of Dr Boggs' paper We also found two cases recorded in literature in which the body was associated with the clinical picture of pernicious anemia There was a total of thirty three cases due to all causes While there are many conditions in which this body may be found in the urine, yet in any case in which we have clinical symptoms referable to multiple myelomas, the presence of this body in the urine should be regarded as a diagnostic feature On the other hand, we cannot assume to day that the presence of this protein body in the urine, in any case in which there are no symptoms pointing to multiple myelomas, has any diagnostic significance I believe with Dr Boggs that we are justified in assuming that protein urine is absolutely diagnostic of disease of the marrow of the bones, and perhaps we can go no further That there are associated with most of the cases well marked and progressive phenomena, as asserted by a number of writers, does not seem to have been true of the cases of Dr Boggs or of Dr Boston's and mine With Dr Boggs, I believe that routine examinations of the urine would reveal not only the protein body, but also other rare morphologic elements, more frequently than at the present time are observed

DR G J SAXON The discovery of the Bence Jones protein in 1847 and the failure to attach any clinical significance to it until 1889, when Kahler and Huppert reported a case of multiple myeloma from clinical and chemical aspects, respectively, is a sad illustration of the degree of enthusiasm which often greets the efforts of the laboratory worker Moreover, not until 1903 was any systematic effort made to collect the cases exhibiting this protein This was done by Anders and Boston Dr Boggs' advice to suspect the presence of this body in bone conditions should be kept in mind Two years ago I examined the urine of a patient having carcinomatous metastases of the ribs, vertebrae and both femurs from a primary involvement of the mammary gland, and while I did not find it, I am not discouraged at not having done so I might mention certain differentiating features of this substance Unlike heteroproteoses, it is soluble in water Unlike other proteoses it is controvertible into metaproteins, is coagulated at low temperatures, yields protoproteose on gastric digestion and is not acted on by erepsin, unlike all soluble proteoses, it does not dialyze through parchment paper

DR. THOMAS R BOGGS Answering Dr Randall I will say that there is confusion in the description of the characteristic multiple myel [illegible] ect what is found in this type of tumor, [illegible] th this protein body, is a loosely arranged sarcomatous tissue of stroma cells which contains also more or less evidence of abnormal growth of the elements of the blood, that is, the ancestral types of leukocytes and red cells.

The inquiry concerning the normal kidney and the excretion of this body touches one of the most interesting physiologic questions, which is, however, too large to be entered into in detail. Why a kidney will permit the passage of this body with all the characteristics of a heavy protein molecule, and hold back the albumin and globulin of the blood is interesting but cannot at present be definitely explained. The relation of nephritis to this particular substance is not settled, but it is significant that large proportions of the cases coming to autopsy have not shown any characteristic nephritis. In our cases we are dealing with something different from the ordinary associations of the disease, that is, a different kind of tumor process, and the urine of our patient had not only this peculiar protein substance, but the serum albumin as well. We did not have an opportunity to study the kidneys. I believe that they would have shown the pathology of nephritis. Dr. Anders asked about the blood count. The leukocyte count was 9,000, with only a mild grade of anemia.

Gastric Dyspepsia Due to Intestinal Diseases, and Intestinal Indigestion of Gastric Origin

Dr. Thomas R. Brown, Baltimore: I studied a series of cases of achylia gastrica with symptoms entirely intestinal, notably, diarrhea, and a series of cases of duodenal ulcer, and eighteen cases of chronic appendicitis, in each of which groups the symptoms were entirely gastric. It is of great importance to examine the gastric contents after the test meal in chronic intestinal cases, in considering the possibility of duodenal ulcer, and to examine gastric contents and stool carefully in cases regarded as gastric dyspepsia, and also in such cases to make a careful examination of the blood and careful temperature observations to determine if the basis of the condition is not some inflammatory process in the region of the appendix.

DISCUSSION

Dr. Alfred Stengel: Just as cases of achylia gastrica often give rise to intestinal symptoms, I have found that gastric ptosis sometimes causes periodic attacks of diarrhea similar to those which occur in achylia gastrica and are relieved in some cases by a proper measure of support, by a reduction of irritation which takes place in these cases of marked gastric ptosis. Many cases of gastritis are due not to the condition of the stomach but to the condition of the colon; these are benefited by treatment directed to the intestinal tract rather than to the stomach. Cases in which it has been shown that there is no gastric or duodenal ulcer demonstrate the fact that the hunger pain has not the absolute importance attributed to it. The pointing out of this important symptom is a distinct advance in diagnosis which has been given to us by the surgeons, but it is not so diagnostic as maintained by Moynihan and many other surgeons following him.

Dr. William E. Robertson: Achylia gastrica is one of the few gastric diseases that give striking and positive laboratory findings. The difference between benign achylia and the achylia of gastric carcinoma occurred to me some years ago and in thinking over sections of carcinoma that I have seen I was struck by the numbers of polynuclear cells found about the periphery of the growth. This led me to believe that we might find them in the gastric contents and afterward, after lifting a test meal and washing out the stomach, I found pus cells even where there was no ulceration of the growth. I had an opportunity of proving this five years ago in an operation on a woman. There was a small non-ulcerative growth on the lesser curvature near the anterior wall. This was sectioned and great numbers of polynuclear leukocytes were found in the periphery. Partial gastrectomy was done and the woman is still living.

Diagnosis and Treatment of Obscure Cases of Pyelitis and Hydronephrosis

Dr. Guy L. Hunner, Baltimore: Many cases are overlooked and recover spontaneously. From this fact we may infer that the treatment should usually begin along medical and hygienic lines. Many cases are not diagnosed, and the patients continue in ill health. Too often the physician fails to examine a catheterized specimen of urine or fails to attribute sufficient importance to the finding of bacteria and leukocytes in such specimens. A marked infection of the kidney pelvis may be present without albuminuria and without pyuria. On the other hand, a marked pyuria may exist for years without apparent injury to the patient's health. Many cases are diagnosed and treated as some other disease, particularly as typhoid fever and malaria. Certain cases of pyelitis are diagnosed and treated as such when the pyelitis is secondary to appendicitis. Pyelitis secondary to ureter stone and particularly cases secondary to ureter stricture are sometimes treated as pyelitis without attention to the cause. Kidney pain may be due to hydronephrosis in cases with normal urine, the hydronephrosis being due to ureter stone or stricture. The literature ascribes a congenital origin for too many of these cases. Gonorrheal periureteritis is probably the cause of a few, and the former presence of a stone undoubtedly accounts for some cases of stricture. Some cases of stone and many cases of ureter stricture may be traced back to infections elsewhere in the body, as in the tonsils.

After the failure of medical and hygienic measures I would recommend the semisurgical methods of pelvic lavage for the pyelitis cases and of dilatation of the ureter for most of the ureter stricture cases and for some cases of ureter stone. All of my cases of colon bacillus infection of the kidney pelvis have been cured by lavage with silver nitrate solution. I use a 1:500 solution of silver nitrate without appreciable ill effects. I am convinced that the silver nitrate solutions are not efficient in the cases of *Staphylococcus aureus* infections. For these I am now using a solution of formaldehyd in 1:2,000 strength, using the commercial formaldehyd as the standard. Many patients do not break down the hexamethylenamin preparations sufficiently to cause antiseptic quantities of formaldehyd in the urine. For dilating ureter strictures I prepare a renal catheter with different sized bulbs of wax placed about 5 cm. back of the tip of the catheter. These bulbs are eventually made as large as 5 mm. diameter if the stricture shows a tendency to contract.

DISCUSSION

Dr. Norman B. Gwyn: Once the suspicion of pyelitis has arisen we should at once start vigorous medical treatment, and move the patient to some place where the ureters can be catheterized carefully. While catheterization is being done, the other essential feature of diagnosis should be carried out. Skiagrams of the distended pelvis of the kidney should be taken. A vaccine can be prepared from the urine and a careful bacteriologic culture made, and if we suspect tuberculosis an inoculation can be done.

Dr. Damon Pfieffer: Medical measures, in the majority of cases, are more or less futile. This is supported by a great number of the cases which Dr. Hunner has cited to-night. I believe that free drainage is the essential cause of the recovery of most of these cases. The question of diagnosis is of supreme importance.

Hygiene, Business and Government.—That health is the basis of all wealth, power and happiness is plain to any one. That business and government have for so long neglected to place hygiene in the front of all practical agencies for good, simply declares that those in charge of business and government have not yet risen to a full understanding of the situation they are trying to control. John Fiske remarked, "It takes a thousand years to raise the human family a single notch." In view of the tardiness of business men and those in control of government to grasp the business and governmental importance of hygiene it would seem that Fiske much underestimates the time. Münsterburg said, "Hygiene can prevent more crime than any law." Disraeli, the practical statesman and empire builder, said, "The care of the public health is the first duty of the statesman."—J. N. Hurty in *Am. Jour. Public Health*.

A MEDICAL COLLEGE IN VENEZUELA

Since the last publication of the list of foreign medical schools, the Council on Medical Education has received word from two different sources, regarding the medical school located at Caracas, Venezuela One of the accounts is in the article on "Medical Education in South America" by Dr Jacob Frank which appears in this issue The following is the account received from Dr Rawson J Pickard, of the Colon Hospital, Canal Zone

"The Universidad Central de Venezuela is one of the oldest universities of the western hemisphere—that at Lima, Peru, is the oldest—but the medical school was not organized until 1800 by Dr Vargas, the 'Father of Medicine in Venezuela,' to whom a statue is erected in the Plaza Vargas in La Guayra, his birthplace, and another in the patio in the university building in Caracas, about which are the medical lecture rooms

"The course takes five years, the first two spent on the fundamental sciences, the second two on anatomy, bacteriology, pathology and clinics, leading to the degree of 'Bachiller' The last two years of the course are spent as extern and intern in the Hospital Vargas, services being chosen by competitive examination The hospital, reached by a trolley line, is on a foothill of the wooded mountain chain which lies between Caracas and the Caribbean Sea The wards are in pavilions at right angles behind the offices and dispensary forming the facade Flower gardens lie between, the windows scarcely ever need be shut, and convalescents can look out from the veranda connecting the pavilions over the red roofed city to the mountains that hem in the green valley of the Guayre

"The laboratories are well equipped The director, Dr Henriquez, demonstrated *Spirochæta pertenuis* from some cases of yaws in the wards There is a plague laboratory, with a glass cabinet containing rubber sleeves for dissections, etc In the museum is much material, especially for the study of tropical pathology The hospital is of 350 beds, charity, with about 3,400 yearly admissions These, as well as the dispensary clinics, draw from the country for considerable distances, besides from the 80,000 population of Caracas Necropsies are optional Nursing is done under the direction of French nuns, it is not at all of American standard.

"The chief surgeon, Dr Acosta Ortiz, invited me to see a hysterectomy, done with a rapid technic and neatness Several things were at variance with American custom Instead of a laparotomy sheet and many towels the field of operation was narrowly bordered by gauze The instruments were kept in a metal dish and sterilized by burning alcohol on them Gloves were not used, owing to a prohibitive tariff

"Fifteen or twenty students who were crowded about the operating table courteously made room for me next the operator, pressing so close that I momentarily expected to be touched by him There was a 'new' woman present, a senior, certainly a great rarity in Spanish America She spoke English and intended to take the year of foreign study, which adds so to prestige in New York.

"Spinal anesthesia was used here commonly long before Jonnesco's tour through the States The Spanish are almost too ready to try the new Statistics from tropical writers, however, are quite favorable to this anesthesia, and it is used freely Several articles appeared in *El Tiempo*, a daily, by Dr Yanes, explaining the use of stovain, and the simplicity of carrying this anesthetic which enables one to be operator and anesthetist He used the spinal fluid withdrawn as the solvent in several minor operations which I saw, 'to obtain an isotonic solvent'

"Text books were chiefly in French, with some in English and German, on account of the lack of good authors in Spanish The similarity of the language to Spanish and the lucidity and simplicity, especially of medical French, give that language the preference They read, translated into Spanish, with the speed of their own language, besides, languages are not taught here as mental exercises merely

The medical students publish a small monthly review, *Revista de la Sociedad Vargas de Estudiantes de Medicina* Several presented me by Dr Ascanio Rodríguez contained articles by him on 'Las Pascuas Azules,' a morning glory, as a delicate indicator Other articles were on bronchitis in cattle caused by *Strongylus micrurus*, by Señor Rángel, and there were book reviews There was a marked tendency to philosophical discussion and to oratory

"The university building is of Gothic design, resembling, in plaster, some of the buildings of the University of Chicago and somewhat incongruous beside the wide tree lined boulevard, in which trolley cars ran past long burro trains Besides writing a thesis, graduates deliver an oration in an imposing room, the *paraninfo*, gorgeous with red velvet hangings Here in the presence of classmates, faculty and friends, he reads into life the ideals that in Spanish America are all the nobler for the sordid contrast to the practical life without Good luck to them Their lives, efforts and brilliant intellects are terribly wasted by struggling with the uncertainties of their social fabric"

Louisiana November Report

Dr A B Brown, secretary of the Louisiana State Board of Medical Examiners, reports the written examination held at New Orleans, Nov 4 6, 1912 The number of subjects examined in was 10, total number of questions asked, 100, percentage required to pass, 75 The total number of candidates examined was 49 of whom 33 passed and 16 failed One candidate was licensed through reciprocity The following colleges were represented

College	Year Grad	Reciprocity with
University Medical College, Kansas City	(1896)	Missouri

ANATOMY

1 Name the muscles that move the eyeball give their nerve supply 2 Give origin course and distribution of right recurrent laryngeal nerve 3 Give relations of brachial artery and name its branches 4 Name arteries which supply the thyroid gland 5 What are the two kinds of bone tissue and where is each found? 6 What muscles connect the scapula with the trunk? 7 What tends to prevent anterior displacement of the elbow joint? 8 Describe briefly the circle of Willis 9 Name muscles of gluteal region and give their origin and insertion 10 Describe the radius and its muscular attachments

CHEMISTRY

1 Define atomic weight (b) molecular weight (c) explain the terms reaction and reagent 2. What elements belong to the halogen group and why are they so called? 3 What is starch (b) properties (c) by what test can it be recognized? 4 Explain the phenomenon of respiration from a chemical standpoint. 5 What is the specific gravity of healthy urine? (b) How is the total amount of solids approximately estimated from the specific gravity? 6 Describe a test by which urea may be determined quantitatively in the urine 7 What is the chemical antidote for corrosive sublimate (b) sulphuric acid (c) caustic potash? 8 *What are enzymes? (b) Name the proteid hydrolyzing and starch hydrolyzing enzymes.* 9 Name the several tests for sugar in the urine and state the one you consider the most reliable and why 10 Give a chemical test for blood

PATHOLOGY

1 What is the difference between (a) anemic infarct and (b) hemorrhagic infarct? 2 Differentiate pathologically between (a) lobar pneumonia and (b) lobular pneumonia, as seen under the microscope 3 Describe the microscopic changes occurring in the kidney in acute diffuse nephritis 4 Describe the mode of action of the phagocytes 5 What are the characters of tumors in general? 6 Describe the healing of a compound fracture of a long bone 7 What part of the spine is affected by Pott s disease? Describe the pathologic changes taking place in the bone in Pott s disease 8 What pathologic changes occur in acute suppurative arthritis (metastatic, not traumatic)? 9 Describe the tubercle bacillus and *give a method for determining its presence in sputum* 10 What is an autogenous vaccine ? On what principle or principles is vaccine therapy based?

PHYSIOLOGY

1 Define anabolism and give examples of anabolic changes 2 What are the functions respectively of (a) the mouth (b) the stomach (c) the small intestines (d) the large intestines in the alimentary process of absorption? 3 Describe briefly the physical and morphologic characters of the leukocytes (white blood-corpuscles) 4 What is a polynuclear leukocytosis and what is its physiologic and pathologic significance? 5 State briefly the causes of the first and second sounds of the normal heart 6 What is the distinction between secretion and excretion? Give examples of each 7 What are the constituents of sweat? 8 What are the constituents of the intestinal juice and what is their action in digestion? 9 What are the functions of the spinal cord? 10 Give the distribution and the function of the glossopharyngeal nerve

THERAPEUTICS

1 What are the therapeutic uses of iodin and the iodids, and how are they administered? 2 When and how should iron be administered? 3 For what medicinal purposes are mercuric chlorid and mercurous chlorid used? 4 What are the indications for the use of chloral hydrate and how is it administered? 5 What ammonium salts are used as expectorants and what is their action? 6 How would you treat a case of acute opium poisoning? 7 What are the indications for the administration of nitroglycerin and how is it administered? 8 What are the uses of cinchona and its alkaloids? 9 When and how would you administer amyl nitrite? 10 In what conditions and how would you administer potassium bromid?

PHYSICAL DIAGNOSIS

1 How would you differentiate between an abscess of the liver and acute hepatitis? 2 Define vocal resonance and state its significance in pulmonary *diseases 3 What are the physical signs of* pericarditis with and without pericardial effusion? 4 Differentiate between *inguinal hernia and hydrocele of the cord* 5 Name the commonest causes of true dyspnea and what are the physical signs of progressive dyspnea? 6 Give the differential diagnosis between paralysis agitans and tabes dorsalis 7 What are the commonest causes of and how would you diagnose unilateral facial paralysis? 8 Differentiate enlargement of the cervical glands (cervical adenitis) due to (a) tuberculosis, (b) syphilis (c) malignant disease (d) Hodgkin s disease 9 What are the physical signs of mitral regurgitation when compensation is established? 10 How would you differentiate (a) biliary colic (b) renal colic (c) floating kidney?

SURGERY

1 What are the causes of gangrene? 2 Differentiate between typhoid fever and appendicitis 3 What is coxalgia? Give treatment. 4 Give treatment of an acute infection of the hand 5 *Describe and give treatment of Colles fracture* 6 Diagnosis and treatment of strangulated inguinal hernia 7 What is a carbuncle? Give treatment 8 Give the different forms of dislocation of the shoulder Describe how you would reduce the dislocation 9 What is hyperthyroidism? What operation may be indicated in such a case? 10 Diagnose pleuritic effusion purulent and non purulent.

OBSTETRICS

1 Name the joints of the obstetric pelvis 2 What is the perineal body and what are its functions? 3 What conditions justify the irrigation of the puerperal uterus? 4 How would you manage a breech presentation? 5 What is version? (b) State two conditions that would require it 6 What signs in delayed labor are indications for the use of forceps? 7 What conditions maternal and fetal would justify the induction of premature labor? 8 Treat a case of puerperal eclampsia. 9 What is involution and when is it completed? (b) Subinvolution and its treatment? 10 What are the signs of fetal death *in utero* and what treatment is necessary when such a condition exists?

GYNECOLOGY

1 Distinguish symptomatically between uterine carcinoma and uterine fibromyoma (b) On what does the possibility of permanent operative cure in cancer depend? 2 What essentials are to be followed in operating *for secondary repair of the completely lacerated* perineum? 3 What are the principal causes of pelvic peritonitis? 4 Describe the blood supply of the uterus. 5 What are the principal causes of dysmenorrhea? 6 Of what pathologic significance is the retroverted uterus in the virgin female? 7 Describe the mechanism of uterine prolapse What surgical treatment will you apply in cases of complete procidentia complicated with cystocele and rectocele? 8 Differentiate between uterine polypus and inversion of the uterus 9 Why is gonorrhea in women so difficult to *cure? 10 Describe the vulvovaginal (Bartholin s) glands*

HYGIENE

1 At what temperature would you keep a sick room and how would you ventilate it for a person with pneumonia? 2 In dormitories, what should be the minimum of air space for each occupant? 3 How would you disinfect typhoid excreta? 4 How would you disinfect a room after a case of scarlatina? 5 Give hygiene and general care of a case of pulmonary tuberculosis to prevent infection of others 6 Give general directions for the care of public schools and care and inspection of school children 7 What diseases are propagated by drinking water? How may impurities in water be detected? 8 Name four diseases that may be transmitted by milk. 9 What is an epidemic disease an endemic disease a sporadic disease? 10 What deleterious gases accumulate in ill-ventilated rooms?

Book Notices

HANDBUCH DER GESAMTEN MEDIZINISCHEN ANWENDUNGEN DER ELEKTRIZITÄT EINSCHLIESSLICH DER RÖNTGENLEHRE. Herausgegeben von Prof Dr Med. H Boruttau Privatdozent für Physiologie an den Universität Berlin und Prof. Dr Med L Mann Privatdozent für Nervenheilkunde an der Universität Breslau Volume 2 Part 2 Paper Price 30 marks Pp 1102 with illustrations. Leipzig Werner Klinkhardt, 1911

The first volume of this work was reviewed in these columns when it appeared, some months ago In this, the second volume, the therapeutic uses of electricity are discussed

In considering the therapeutic value of electricity one must distinguish clearly between the effects of electricity as a physical agent and the effects of electricity *per se* as for instance in the use of the ordinary galvanic or faradic current or the so called franklinization That distinct local effects of a physiochemical nature may be produced by electricity is unquestioned, but it is doubtful if any such things exist as intangible and mysterious therapeutic effects in general conditions or even in local conditions On this phase of the subject some of the contributors to this volume at times are quite frank Thus, in a chapter devoted to the factors which have a beneficial influence, it is stated, concerning the beneficial effects of the electric bath, that the bath itself is the great therapeutic factor and probably of much greater importance than the electricity Under electric massage it is stated that a scientific foundation for such a procedure has not yet come to hand

'Suggestion may be regarded as an important curative factor in the different electrotherapeutic methods" The suggestion may be intentional or unintentional When in a hysterical paralysis, contracture or anesthesia, the paralyzed limb is treated with the static spark or with the faradic brush or with the four celled bath, it is not electrotherapy but intentional suggestion" That the author himself doubts the therapeutic value of electricity is well shown by the following sentence "In the discussion of the effects of electricity I have shown in what manner one must *imagine* the curative effect of the electricity *in case such an effect really exists"* These quotations indicate that one must not place too much confidence in the use of electricity, or expect too much from it, as a therapeutic agent.

Part 3 of the volume treats of electric lighting, electric heating and electric motors as used by the physician, and of electrolysis, cataphoresis and phototherapy These chapters, although very technical, are of great scientific and practical interest The work as a whole deals with the subject of electricity in a most thorough and comprehensive manner

Studies in Cancer and Allied Subjects Pathology Conducted under the George Crocker Special Research Fund at Columbia University Volume II Boards Price $5 net Pp 267 New York The Columbia University Press 1912

This book consists of twenty seven articles by Isaac Levin, M J Sittenfeld, Robert A Lambert, Frederic M. Hanes, Robert T Frank and A. Unger, previously published in such easily accessible journals as the *Journal of Experimental Medicine, Surgery, Gynecology and Obstetrics*, etc, and all dealing with the results of investigation into some phase or other of "the cancer problem" Prof W G MacCallum writes an introduction The collection in this way of the articles published from one laboratory or institute is of some convenience to active workers in the same field, and it also forms a more or less imposing monument, in appearance at least, to the institution from which it is issued, yet there is occasion for the question whether in view of the expense and the increased labor on the part of libraries such republication really is worth while In the United States this kind of republication is prevalent at present In many cases it is feared that the chief result is accumulation of books that are not consulted No doubt the great value of the investigative work represented in the volume under consideration is such as to warrant republication, but no matter how epochal the work, it would not justify publication in the form selected in this instance The volume is so large as to be unwieldy, many book shelves will not receive it standing, and the blank margins are of such unusual width that considerably less than half of each page is occupied by print, hence more than one half of the book is unused paper That the Columbia University Press could become responsible for such an example of pure waste and lack of judgmént in book making passes understanding

A Second Study of Extreme Alcoholism in Adults with Special Reference to the Home Office Inebriate Reformatory Data By David Heron D Sc. University of London Francis Galton Laboratory for National Eugenics Eugenics Laboratory Memoirs XVII Paper Price 5 shillings Pp 95 London Dulau & Co 1912

As social questions are to be solved not by opinion but by statistical facts, the data collected by Dr R. Welsh Branthwaite, inspector under the British inebriates acts, marked an advance in the study of inebriety A detailed account was given of 166 men and 865 women inebriates Heron's memoir is based on a consideration of these women inebriates in view of their larger number and because the problems of extreme alcoholism concern women to a greater extent than men inebriates Figures showing the relative intensity of drunkenness in men and women prove that

men, at most differ as Heaven and Earth
But women worst and best as Heaven and Hell

After an exposition of the material, Heron compares the various characteristics of inebriates as a whole, as modified by different intensities of alcoholism, and as contrasted with mental defects in the general population He has taken pains to avoid the pitfalls in the path of interpreters of statistics, and his presentation of the subject will interest students of the social questions He concludes with a survey of the results of reformatory treatment, and makes practical recommendations for further inebriety legislation

The Business of Mining A Brief Non Technical Exposition of the Principles Involved in the Profitable Operation of Mines By Arthur J Hoskin M L. Cloth Price $1 50 Pp 224 with illustrations Philadelphia J B Lippincott Company 1912

Those physicians, who are inclined to invest rashly in mining stocks and enterprises, might find it advantageous to read this little book on "The Business of Mining" After describing in a more or less non technical way the varieties of mines and methods of mining, the author devotes considerable space to a sensible discussion of mining as an investment, giving some needed attention to the genus "promoter," a study of whose methods may be of interest and value to the would be investor

Miscellany

Supervision of Communicable Diseases in New York

The sanitary and public health control of the 5,100 000 persons comprising the population of New York City must of necessity furnish not only much information of general interest but also many object lessons of success and failure which can well receive wide attention from public health officers and sanitarians The October bulletin of the New York Department of Health reviews the organization and work of its division of communicable diseases, a division instituted in 1892 as a defensive measure against a threatened invasion of cholera When this danger had passed, the division undertook the study and control of diphtheria and made bacteriologic examinations for tubercle bacilli for private physicians, together with routine laboratory reports on suspected cases of typhoid, malaria and meningitis The sanitary supervision of these diseases followed naturally

In 1905 the division was put on its present basis Its functions now include (1) the sanitary supervision of tuberculosis, typhoid, cerebrospinal meningitis, pneumonia malaria, puerperal septicemia, abortion, erysipelas, poliomyelitis and venereal disease, (2) the direction of tuberculosis camps and clinics, (3) the administration of diphtheria antitoxin and intubation, (4) the direction of the diagnosis laboratory and collection of specimens throughout the city

The administration of diphtheria antitoxin for curative and prophylactic purposes and the practice of intubation have been maintained since 1895 In 1911, 6,167 patients were injected with antitoxin Tuberculosis is reportable and the registration and supervision of this disease are facilitated by a system of health department clinics for tuberculous patients In these tuberculosis dispensaries a total of 28,570 persons received treatment in 1911, of whom 16,562 were new cases In 1906 an original and effective line of work was begun by fitting out an abandoned ferry boat as a day camp for tuberculous patients living at home This work has since been extended to include two other camps under the department and several connected with hospitals In these camps a hot dinner is provided at noon, and lunches of milk and eggs in the morning and afternoon Open air classes are conducted for the children, the equipment being provided by the Department of Education The Department of Health conducts a tuberculosis sanatorium at Otisville, N Y, for admission to which there is always a long waiting list

The sanitary supervision of typhoid includes the investigation of all cases by inspectors, who visit both the patient and his physician, more complete reports from the physician on the termination of the disease and a thorough investigation of the possible sources of infection in each case, whether by contact or through the food supply Pin maps of each borough show any unusual grouping of cases and may point out the source of infection Also a tabulated record is kept of the date of onset and the milk supply in each case The division is preparing to make prophylactic typhoid vaccinations on request or in local epidemics, and it is expected that in the near future removal to hospital will be required when conditions at home preclude proper preventive measures In 1911 3,080 cases of typhoid were reported and 13,521 inspections were made

A similar and even more rigid supervision is maintained in cerebrospinal meningitis and anterior poliomyelitis Reports are required of all cases of malaria, pneumonia, erysipelas, abortion and puerperal septicemia, but patients are not visited Cases of malaria reported are investigated to determine the validity of the diagnosis and whether it is supported by laboratory findings Reports of venereal disease have only recently (1912) been required These reports are filed but are not open to the public The laboratory will soon be prepared to make all examinations requisite in connection with these diseases The work of the diagnosis laboratory in 1911 included 40,048 sputum examinations, 68,868 throat cultures 10,549 examinations of typhoid blood, 2,376 of malarial blood, 2,926 of typhoid urine, besides numerous examinations of pus and spinal fluid specimens and miscellaneous preparations

The budget of the division of communicable diseases for 1912 was $435,397 00

Sterilization of Drinking Water with Minimal Amounts of Calcium Hypochlorite—The method of sterilizing water according to Dserschgowski's technic has recently been tested at Cronstadt, Russia, and Antonowsky reports the results in the *Ztschr f Hygiene*, 1912, lxxii, 421 His aim was to determine the relative resistance of cholera and typhoid germs and the colon bacillus to amounts of chlorinated lime in the water too small to affect its taste His experiments demonstrated, he states, that the effectual agent in sterilization of water by neutral solutions of chlorinated lime is the oxygen The effect consequently depends on the oxidizableness of the water rather than on the proportion of chlorinated lime. With addition of catalyzers, such as hydrogen or manganese dioxid, the bactericidal action of chlorinated lime is increased. With a proportion of 0 0025 gm active chlorin to the liter, ten minutes are required for partial destruction of the germs and checking of the growth of the others, this interval is necessary on account of the slowness of the chemical changes involved, the gradual release of hypochlorous acid in the solution of chlorinated lime He regards the method on the whole as a good help in combination with mechanical measures for purification of drinking water

The Dangers of Uterine Fibroids—It has been the custom in past times to consider fibroid tumors of the uterus as harmless neoplasms, to be put up with, lived with and finally to be buried with Further we have been taught to believe that the latter supposition is in no way hastened by the presence of a fibroid tumor So ingrained was this view that even quite recently an eminent authority stated in a paper that death from uterine fibroids was the rarest occurrence The more, however, we see of gynecologic and obstetric practice, the more in my opinion, we must recognize that uterine fibroids bring in their train very serious disabilities lead to much chronic invalidism, and play a by no means small part in hastening the demise of many individuals —Thomas G Stevens in *Clin Jour*, London

Medicolegal

Validity of Act Giving State Board of Health Authority Over Water-Supplies

(State Board of Health vs City of Greenville (Ohio) 98 N E R 1019)

The Supreme Court of Ohio holds that the act of the General Assembly passed April 7, 1908, entitled "An act to authorize the State Board of Health to require the purification of sewage and public water supplies and protect streams against pollution," now being Section 1249 et seq of the General Code of Ohio, is a valid and constitutional exercise of the police power of the state The court says, among other things, that this legislation is designed to preserve and protect the public health and comfort, and therefore falls directly within the police power of the state This power includes anything which is reasonable and necessary to secure the peace, safety, health, morals and best interests of the public

In granting to a municipality certain powers to be exercised for the benefit of the public health of that municipality, the state has not relinquished its authority and control in this important particular over any of the territory comprised within the limits of the state The duties and powers of the State Board of Health extend throughout the state irrespective of political divisions or territories embraced within municipalities The general provisions for the preservation of the life and health of the people of the state are no more suspended in the territory comprised within a municipality than are the criminal laws of the state and this case would illustrate the folly of a state delegating to any municipality full and complete control of matters pertaining to the public health A municipality might then in the preservation of sanitary conditions in its own territory work incalculable mischief to the health and comfort of people living in adjacent territory To prevent this being done, it is primarily necessary that there should be one central authority clothed with the power of affording equal protection to all

The state does not seek to control the discretion of the municipal authorities in this matter, but, on the contrary, refuses to commit to them any discretion touching the particular matters committed to the care and control of the State Board of Health In so far as they are charged with any duty in reference to the carrying out of the orders and directions of the State Board of Health, they are ministerial officers only, and it is fully settled that a public officer may be required to perform a ministerial act, and that a failure or refusal by such officer to perform a ministerial act may be made a criminal offense and punished as a misdemeanor

The provision in this legislation by which a municipality may challenge the judgment of a State Board of Health and submit the question to a board of arbitration composed of men skilled in sanitary work is a most liberal provision so far as municipalities are concerned, and far more liberal than many of the statutes relating to the powers of a State Board of Health There is no theory on which a mere agency of the state has a right to litigate the right of the state to enforce, through any agency it pleases, sanitary rules and regulations for the preservation of the health and comfort of all the people of the state

Nor is this legislation unconstitutional because it delegates the taxing power of the city to the State Board of Health

If the city possessed the absolute right to discharge its sewage into a living stream of water, thereby polluting the same and destroying all riparian rights below and creating a menace to the health and comfort of those living on the banks of this stream below the point of discharge, then it might be said that any change in the manner of sewage disposal would not be for the benefit of the city, but for those citizens of the state residing below the outlet of the city sewers But the city has no such absolute right, and whenever this condition of affairs exists it is right and proper for the state to interfere and prevent it from a further continuance of this nuisance, and, the city then having no other means for the disposal of its sewage, it is primarily for its benefit that such disposal plant must be established.

The health of the inhabitants of the city is still a matter of concern to the state, and of such vital concern that the General Assembly has not thought proper to commit it exclusively to the control and discretion of men who may or may not have any particular ability or experience in sanitary affairs The loss of a single life is a direct economic loss to the state, and therefore it wisely refrains from committing to inexperienced people final discretion as to the means and methods of preserving the life and health of its citizens, but, aside from the concern of the state for the health and comfort of the residents of any one city, its vigilance seeks to serve a larger purpose Cities are no longer inclosed by stone walls and separate and apart from the balance of the state The sanitary condition existing in any one city of the state is of vast importance to all the people of the state, for, if one city is permitted to maintain insanitary conditions that will breed contagious and infectious diseases, its business and social relation with all other parts of the state will necessarily expose other citizens to the same diseases But with the wisdom or folly of withholding from the local authorities final discretion over these matters, the court is not concerned It is beyond question the right of the General Assembly to do so, and the court need not, and ought not, to inquire what motives moved it in withholding such power

The disposal plant is for the benefit of the residents of the city It is primary duty of the city to provide for sanitary disposal of its sewage, and it is not in violation of any provision of the constitution that it should bear the entire cost of erecting and *maintaining a purification plant, and to require it* to do so is not an arbitrary unreasonable, or unfair exercise of the police power of the state.

8 Public Health—Past and Future H W Hill Minneapolis
9 The Trend of Medico-Social Effort in Child Welfare Work W C Phillips New York.
10 Recent Typhoid Outbreaks in Kona Hawaii E S Goodhue Hawaii

1 **Cold Storage and Public Health** —Sedgwick believes that, by cold storage to day, rightly supervised by boards of health, as it should be, the public health has been and will be immensely promoted The public health will also be promoted indirectly through the cheapening of cost of food in two ways first, by saving what would have been lost at one season and keeping it over to another, when prices would have been much dearer than if it had not been kept and the supply at the later period increased, and second, by encouraging production

2 **Physics of Refrigeration** —Successful refrigeration, Bryce points out, involves that goods shall be taken from cold storage in the pink of condition, hence, this demands that perfectly fresh, matured products shall at the beginning be placed in the cold storage and when so placed given the most skilful treatment possible during their detention there Being essentially an economic proposition, it means the most careful attention by the engineer in charge of the temperature and relative humidity of the cold storage room, assuring that such be neither too high nor too low The more delicate the thermometer, the greater the success in maintaining evenness of temperature. While the perfection of any product placed in cold storage is a *sine qua non* to highest success, whether hygienic or commercial, yet permanent results must depend on how economically and yet efficiently the mechanical and physical appliances involved perform their work

5 **Refrigeration of Fish** —From the sanitary standpoint, at least, says Pease, the problems in the refrigeration or freezer storage of fish and oysters relate almost without exception to the conditions under which the food or oysters have been caught or gathered and prepared for refrigeration, and to the methods of handling these food products after they have been moved from the influence of processes of refrigeration

6 **Cold Storage and Food Supply** —In order to promote uniformity of legislation by the several states, a thing greatly to be desired in all regulative legislation, the National Association of Food Officials in 1911 gave to a committee of its members the task of drafting a model cold storage bill Barnard is chairman of that committee The committee recognizes the need for legislation first, to protect the public health against the sale of unfit food, second, to prevent cornering of the food supply and consequent unfair prices to the consumer, and third, to insure both to the consumer and to the producer the sale of goods properly labeled The committee defines cold storage as a warehouse for the holding of food products at or below a temperature of 40 F It holds that a cold storage warehouse is an establishment employing refrigerating machinery or ice for the purpose of refrigeration where food products are stored for thirty days or more at a temperature of 40 F It assumes that the states have already at hand machinery for the sanitary control of food producing establishments, and it provides that the operators of cold storage warehouses shall obtain a license from the state board of health for conducting the business after a sanitary inspection has shown the warehouse to be in satisfactory condition In the event a warehouse so licensed becomes unsanitary, it is made the duty of the state board of health to revoke the license The bill provides that a complete record shall be kept of all goods entering storage and that a quarterly report of such facts shall be presented to the state board of health It is believed that such reports will prevent the cornering of the food supply It provides that no article of food shall be placed in storage if not sound and in good condition, or unless it has been prepared in accordance with the pure food and sanitary laws The committee is unanimous in its belief that cold storage legislation should not antedate pure food and sanitary food legislation but rather should follow and supplement it When food is placed in storage the date of entry is plainly marked on the container, and when removed it is again marked No goods shall be held in cold storage for a longer period than twelve calendar months, except under certain conditions referable to the state board of health It provides that goods which have been in storage must be labeled "Cold Storage" in such manner that the consumer knows when he purchases his eggs, for instance, that they are storage eggs It provides that the state board of health may make all necessary rules and regulations to secure a proper enforcement of the law

American Journal of Neurology, New York

November VIII, No 11 pp 567 602

33 *Wassermann Test in Tropics L B Bates Canal Zone*
34 Poisoning by Nitric Oxid Fumes. F C Wood New York
35 *Organic Iodin Preparations Their Pharmacology and Therapeutic Value F C McLean Portland Ore

28 **Influence of Radium on Ferments**—None of the radium preparations used by Brown seemed to have any effect on the autolytic ferment of the liver, although saturated lead chlorid solution appeared to activate it, with diastase the very radio active radium possessed an inhibiting effect, while the less active radium emanations had a stimulating effect, this increasing with the length of time and the amount of fluid used, while this ferment is also markedly activated by the salts in evaporated tap water, with pepsin Brown found a slight inhibiting effect, more marked with very radio active radium, although slight in comparison with the inhibiting effect of saturated lead chlorid solution

30 **Intraspinal Injections of Ringer's Solution.**—An experimental inquiry was made by Carter into the cause of the severe shock which sometimes follows the injection of serum into the subarachnoid space of the spinal cord. The sole object of his investigation has been to determine the mechanical effect on the spinal and medullary centers, of increasing the amount and pressure of fluid in the spinal subarachnoid space For this purpose Ringer's solution has been used, as this contains the different inorganic salts of a real physiologic salt solution and is therefore preferable to the isotonic solution of sodium chlorid commonly called by that name He found that no definite limit can be fixed to which the intraspinal pressure may be increased with safety In some animals serious symptoms developed when it was increased to 10 mm of mercury, while in others this only occurred with a pressure of 50 or 60 mm of mercury The normal intraspinal pressure in dogs varies from 3 to 10 mm. of mercury, or 40 to 135 mm of water A sudden increase of pressure, even though a small amount be given, is more dangerous than a larger amount given gradually by gravity The first mechanical effect of increasing the intraspinal pressure from injections made by lumbar puncture is the cessation of respiration, quickly following it, or coincidently with it there is profound cardiac inhibition, which causes a tremendous and sudden fall of blood pressure The fall of pressure is often so abrupt that it frequently drops from normal to zero within a half minute Atropin removes the cardiac inhibition and restores blood pressure by its paralyzant effect on the cardio inhibitory nerve center Atropin fails to stimulate the respiratory center, while cocain is the most valuable respiratory stimulant for such an emergency

Carter says that these drugs should be given together in full dose before making a spinal puncture or intraspinal injection The injection at the site of spinal puncture would also produce local anesthesia The condition could thus be prevented more easily than it can be remedied after alarming symptoms suddenly develop This is particularly true if chloroform is used as an anesthetic, as the inhalation of chloroform in concentrated vapor produces similar effects and thus makes the condition more serious The fall of pressure is not due to a vasomotor disturbance There is, therefore, no indication for the administration of epinephrin On the contrary, it is positively contra indicated on account of its well known action in producing cardiac inhibition Lowering the intraspinal pressure by allowing fluid to escape from the needle, after the characteristic symptoms develop, fails to relieve the condition The advantage of using atropin and cocain before intraspinal injections consists not only in lessening the dangers of sudden death, but it enables a larger amount of fluid to be injected without producing dangerous symptoms from the mechanical effect This is a great advantage in administering antimeningococcus serum, as its action is chiefly a direct, local one on the living bacteria and the benefits are in proportion to the amount administered

32 **Pathogenesis of Purpura Hemorrhagica**—By comparing symptoms and blood findings in all patients observed during a period of three years, who displayed a pathologic tendency to bleed, Duke succeeded in picking out a certain group of cases which presents a characteristic clinical picture, which is due wholly or in part, it is believed, to an enormous reduction in the number of blood platelets The disease in its severer form almost constantly presents the following symptom complex 1 Purpura of one or two types—petechias or ecchymoses 2 Hemorrhage from mucous membranes 3 A tendency to bleed from every vascular lesion, no matter how produced In consequence of this tendency, the bleeding time is very greatly prolonged, often exceeding two hours 4 A normal coagulation time 5 A firm blood clot 6 In consequence of the absence of platelets, a clot which does not retract and extrude serum In all cases (seven) seen by Duke showing the above picture, the number of platelets was reduced almost to a point of absence Counts were all below 10,000, and as a rule, below 1,000 (The normal platelet count varies from 200,000 to 400,000)

The disease in its milder form presents a different picture The most common symptoms in the milder cases are ecchymoses following slight injury and epistaxis Sometimes neither purpura nor bleeding from normal mucous membranes appears and the only evidence of hemorrhagic diathesis in severe hemorrhage accounted for to a greater or less extent by local causes, for example, continued bleeding from intestinal ulcers, from esophageal varices, profuse and prolonged menstruation, etc The bleeding time in the mild cases is sometimes normal and sometimes slightly or moderately prolonged The coagulation time is normal, the clot firm, retractility diminished The diagnosis rests on the finding of a reduced platelet count It varied, in Duke's cases (six), from 20,000 to 65,000

Hemorrhagic diathesis can be followed best in this disease by determining the bleeding time at frequent intervals The simple observation of purpura, spontaneous hemorrhage, etc, may lead to false conclusions in regard to the general condition, for these symptoms are often due to general and local causes combined. When there was opportunity to make such observations it was noted that the disease appeared when the platelet count fell to an extremely low level, persisted so long as the count remained low and disappeared as soon as the count rose The disease was relieved immediately in two cases by direct transfusion of blood The relief was coincident with an increase in the platelet count, evidently a direct result of the transfusion Symptoms returned when the platelet count fell again

The disease was produced in rabbits by reducing the platelet count with diphtheria toxin This disease appeared the day the platelet count descended to a point of almost complete absence and persisted until the platelet count rose Hemorrhagic diathesis in mild form was brought about with repeated injections of benzol In the latter experiments the count did not descend to such a low level as in the former In a series of thirty eight animal experiments, in which the platelet count was enormously changed with subcutaneous injections of benzol, diphtheria toxin and tuberculin, and also in a large series of cases in humans in which routine platelet counts were made, only those having extremely low counts gave the complete symptom complex described above Several platelet counts between 40,000 and 75,000 were observed in patients who had no marked tendency to bleed This seems to be the level at which patients may or may not have an abnormal tendency to bleed No counts lower than these were observed in patients not subject to hemorrhage The disease has been observed complicating a varied set of diseases—in severe form in lymphocytic leukemia, hemorrhagic small pox, tuberculosis, nephritis benzol poisoning, aplastic anemia and diphtheria The one feature in common in these cases was the low platelet count and the modification of the clot dependent on it, i. e, absence of retractility Purpura hemorrhagica of the type described would seem, therefore, a symptom, not a disease It is caused apparently by any agent which reduces the platelet count to a sufficient degree

35 **Organic Iodin Preparations**—From evidence presented as to chemical nature, absorption and excretion, distribution physiologic action and clinical results, McLean draws the following conclusions with regard to the therapeutic uses of the organic iodin compounds Up to the present it has not been shown that the organic iodin preparations, with the exception of preparations of thyroid, have any specific action in pathologic conditions, except the action of iodin after separation from the molecule The iodized proteins seem to be of advantage for therapeutic use only in so far as they avoid gastric irritation The more stable compounds are apparently not entirely split in the body and are therefore not well utilized, while the less stable compounds have no advantages over the alkaline iodids, either as to local effects, or as to rapidity of absorption and excretion The iodized fats and fatty acids appear to have some advantage when the continuous action of small amounts of iodin is desired. They are more slowly and evenly split, and the amount of available iodin in the blood does not vary from time to time to the extent that it does when the alkaline iodids are administered The use of the iodized fats in such conditions as arteriosclerosis, bronchial asthma, lead poisoning etc, probably has some rational basis, therefore, on physiologic grounds These substances are also as a rule non irritant to the stomach The difference in frequency of iodism is probably due to the difference in the amount of available iodin present in the body at any one time When large amounts of iodin are desired, as in cerebrospinal syphilis, avoiding the danger of iodism would be at the sacrifice of therapeutic efficiency The use of organic iodid preparations with toxic side actions, due to the molecule or its splitting products, should of course be discouraged The products of iodin with the higher fats and fatty acids are generally free from toxic actions

38 **Artificial Pneumothorax in Lung Tuberculosis**—The eighteen months' experience Balboni has had in the treatment of pulmonary tuberculosis in its different stages by artificial pneumothorax has convinced him of its place in the treatment of this disease He says that any one who has had any experience whatever with present methods of treatment for pulmonary tuberculosis must feel a moral obligation to try every new method that promises any degree of success at all, and it becomes a duty to do so when a method of treatment is presented by which good results have been obtained in advanced cases of phthisis

It is to be hoped that with the necessary wisdom, the method will be applied on a larger scale and earlier in cases in which the spontaneous evolution shows a progressive and destructive tendency Phthisiology is not so rich in resources as to justify overlooking a method of treatment that has given such good results

46 **Experimental Studies on Milk**—The results of Schorer's extensive and detailed studies on milk may be summarized as follows Better classes of milk contain little sediment, market milks contain more dirt but fewer cells than certified milks The Tromsdorff tube is a convenient method of examining for dirt and cells It is relatively easy to produce milk of low bacterial content, but the greatest care must be constantly exercised to prevent occasional high counts Increase in bacterial content was more rapid at the higher temperatures, and at a temperature just above freezing there was little bacterial multiplication until after the seventh day but from that time on the increase was rapid Cream on rising carries with it a large portion of the bacteria in milk Separator cream does not take with it as large a portion of the bacteria as does gravity cream When milk was stored and the cream and skimmed milk were not remixed, bacterial multiplication was not as great during the same period of storage as when the milk was mixed repeatedly Of the bacteria in good milks about 30 per cent were acid producers, while 20 per cent of those in inspected and 30 per cent of those in certified and pasteurized milks were protein digesters At the higher temperatures fermenting organisms increased more rapidly in certified milk, but at the lower temperatures the most marked increase was observed in pasteurized milk The percentage of peptonizing types increased only at low temperatures Apparently gravity cream contains the larger portion of peptonizing forms, while the skimmed milk below contains most of the fermenting forms when milk has been refrigerated

On long storage butyric acid and putrefactive odors became marked When mil[illegible] [illegible]ed at low temperat[illegible] the development of [illegible] have [illegible] by acid odors [illegible] me t[illegible] certified and [illegible] Protein dec[illegible] pally at a temperature near the freezing point Adding an equal part of 68 per cent alcohol to milk is an easy and reliable test for the detection of beginning acidification The fear of putrefying organisms in pasteurized milk is not warranted as far as market milk pasteurized by the holding method is concerned While predominance of putrefying bacteria is not the only objection to pasteurized milk, it has been an important one Certified milk, because it contains but little cow manure, is infected principally with spore bearing organisms, it is always well refrigerated, and contains as large a percentage of protein digesting and no more acid forming bacteria than does pasteurized milk The cleanliness necessary to produce certified milk is so imperative and the variation in the production and pasteurization of ordinary market milk is so marked, that certified and pasteurized milks are most variable Inspected milk is apparently more uniform in numbers and kinds of bacteria

47 **Milk Streptococci.**—Streptococci, virulent for animals, but which differ from typical *Streptococcus pyogenes* in a more abundant growth, in being encapsulated and not forming chains and in causing but little hemolysis, Rosenow says occur in predominating numbers in epidemic sore throat of milk borne origin On artificial cultivation these strains sooner or later assume the characteristics of *Streptococcus pyogenes* By placing *Streptococcus pyogenes* in unheated milk it becomes modified so as to correspond to the streptococci in epidemic sore throat The modifications may be accentuated by passage through guinea pigs, and in some cases cultures like those of streptococcus mucosus may result The fact that milk so modifies streptococci is an additional indication of the important part it may play in epidemic sore throat It is not possible to determine whether the streptococci in such epidemics are of exclusively bovine or human origin, they may be of both Milk drawn in a sterile way from normal cows may contain virulent streptococci and pneumococci, hence, "certified milk," while surely less contaminated than ordinary milk, may contain pathogenic bacteria, and the advisability of pasteurization even in this case should be considered, especially during seasons when sore throat is common Butter and cream may contain virulent streptococci

48 **Antibodies in Colostrum and Milk.**—From her experiments, Tunnicliff concludes that normal human colostrum milk contains more opsonins for the streptococcus, staphylococcus and tubercle bacillus than does the later milk, but less than the blood serum Since this is true, it would seem of great importance that the newly born infant should receive colostrum milk

49 **Biochemistry of Tuberculosis** —The authors' systematic consideration of the chemotherapy of tuberculosis rests on an investigation of the permeability of both the tubercle bacillus and the tuberculous lesion for chemical substances of different characters It is shown that compounds of iodin injected into tuberculous animals enter glandular tubercles with readiness, so that the proportion of iodin in such tubercles is usually greater than it is in most other tissues except the kidney, furthermore it is greater in the caseous contents than in the cellular peripheries of the tubercles Tuberculous eyes usually contain much more iodin than their normal mates This property is shown not to depend on any specific character of the tubercle itself, for other necrotic tissues also take up more iodin than normal tissues The explanation offered is that normal cells are not perfectly permeable to iodids (except perhaps kidney cells) and lose this impermeability or semi permeability when killed or injured thus becoming entirely permeable for crystalloids present in the surrounding fluids As the iodin content of the blood increases and decreases with absorption and elimination, so the iodin in the necrotic area, whether tuberculous or otherwise, varies, indicating an absence of any chemical or physical binding of the iodin in such areas A simple, inert, colloid agar, implanted in the tissues, behaves in quite the same way Egg albumin injected into tuberculous pigs is found, by means of the anaphylaxis reaction, to penetrate the avascular tubercules but little if at all, even when present in the blood in large amounts This agrees with the hypothesis that the passage of iodin from the blood into the tubercles is a purely physical matter, the crystalloidal iodin compounds diffusing through the inert colloidal solution of a necrotic area practically unimpeded, while the colloidal egg albumin, according to the law of colloidal diffusion, is practically unable to diffuse through such a colloidal solution No evidence could be found of any tendency for iodin compounds of whatever nature to accumulate in tubercles or other necrotic areas, or to persist in such areas when disappearing from the normal tissues and the blood

50 **Tuberculous Guinea Pigs and Fat-Soluble Dyes** —Fat dyes administered by Corper under various conditions to guinea pigs with tuberculosis never were found within the tubercles This is in favor of the view that the fats of the tubercle are derived from the intracellular fats of the tissues forming the tubercle, and not from food fats or transported depot fats Tubercle bacilli within tubercles in such animals do not become stained with the fat stains Saturation of the animal with common fat dyes has no noticeable influence on the course of a tuberculous infection in the guinea pig The fat stains employed in these experiments (Sudan III, scarlet R, Sudan yellow Sudan brown, Nile blue sulfate) were never found to stain any but depot fats, not being present in the parenchymatous cells whether normal or diseased They caused no apparent harm to the guinea pigs even after being fed to them over 200 days Subcutaneous or intraperitoneal injection of fat dyes dissolved in fats and oils is much less effective in staining the depot fats, than is feeding the stained fats Fat dyes do not pass through the guinea pig placenta to the fetus, or at least the fat of embryo pigs from stained mothers is not stained (corroborating the result of the Gages, Mendel and Daniels) The embryos often show extremely fatty but unstained livers Fat dyes were never observed to pass into the milk of lactating guinea pigs, although positive results have been obtained by others

52 **Antirabic Immunity** —Harris' experiments seem to show that it is comparatively easy to immunize rabbits against rabies by a single intraspinal injection of non infective desiccated "virus," and that the resulting immunity is acquired with surprising rapidity, and is not followed by any ill results

55 **Oxidizing Agents and Phagocytosis** —Sodium iodoxybenzoate, which contains 11 43 per cent of physiologically active oxygen, Arkin found, has a markedly stimulating action on the phagocytosis of streptococcus and staphylococcus by human leukocytes in the presence of human serum, *in vitro* Sodium iodbenzoate, which contains no oxygen, has no such effect This stimulating effect on phagocytosis is related to its germicidal action, which is also dependent on the oxygen combined with the iodin in the molecule Arkin ventures to express the opinion that the opsonin of the serum is probably rendered more active by the oxygen containing substance, for the stimulating effect is exerted only in the presence of serum Therefore, sodium iodoxybenzoate may be of value in some infections because of its stimulating effect on the production of antibodies and on phagocytosis, as well as its bactericidal action Furthermore, a relationship is suggested between oxidation and the process of phagocytosis, for a substance which liberates oxygen readily stimulates phagocytosis, whereas a substance which prevents oxidation reduces phagocytosis

60 **Intraleukocytic Bodies in Scarlet Fever** —Glomset claims that bodies in the leukocytes like those described by Döhle occur in many febrile diseases, and in smaller numbers in other diseases, and even in health The larger part of these bodies are of nuclear origin, and may be produced by shaking the blood. He does not believe that it is justifiable to regard them as having any etiologic significance

62 **Toxic Substances from Pneumonic Lungs** —The action of the toxic substances obtainable from pneumococci and pneumococcus exudates on the blood pressure and respiration in normal dogs is said by the authors to be identical and strikingly like that which is observed in immediate anaphylaxis in dogs Pneumococcus anaphylaxis in dogs does not essentially differ from protein anaphylaxis in general The lesions are also similar The hemorrhages, the effect on the respiration

the extreme grade of cyanosis, especially in the fatal cases, the delayed coagulation of the blood and the presence of carbon dioxid in the stomach indicate that one of the chief effects of the toxic substances is an interference with the normal oxidative processes The toxic substances concerned are probably of the same general nature because the lesions and the effect on the circulation and respiration are so similar, and it makes no essential difference whether they are formed *in vitro*, in the consolidated lung in man, at once in sensitized dogs, or at a later period in normal dogs

16 Psychasthenia A T Schofield and R M Leslie

1 **Avenues of Rheumatic Infection** —Sydenham's chorea and rheumatic fever in Branson's opinion are due to one and the same infecting agent The action of the rheumatic poison on a specifically predisposed central nervous system, he says, produces a characteristic nervous instability which may precede the appearance of choreic movements by some weeks, and may in other cases itself constitute the sole evidence of the choreic tendency, the phase of movements never becoming developed at all The emergence of choreic movements is determined by emotional stimuli acting on a central nervous system thus previously disequilibrated. The commonest avenue of rheumatic infection is the tonsil and next to it the nose The first essential of rational treatment, of rheumatic infection is restoration *of the upper air passages to a healthy condition Irrigation* and thorough cleansing of the nasal passages, combined with antiseptic treatment of the nose and pharynx, should be a routine item of antirheumatic treatment, and the operation of enucleation should be performed without delay on all rheumatic children who exhibit chronic enlargement of the tonsils or of the tonsillar lymphatic glands Chorea is a common sequel of scarlet fever, but the appearance of movements is usually postponed until the patient has left the fever hospital

2 **Human and Bovine Tuberculosis** —The most reliable test which we possess in the process of differentiation between human and bovine tubercle bacilli is the inoculation of certain animals (most commonly the rabbit or the calf) with a small known quantity of the organism under investigation If the infection results in a rapid dissemination of the disease and the speedy death of the animal, Fraser says it may be affirmed that the bovine bacillus is the organism present If on the other hand, the resulting lesions are few and tending to be retrogressive and death ensues after a very considerable interval of time, or from some intercurrent disease, the infection may be classified as human A distinction can be drawn between human and bovine bacilli by the local reaction, as well as by the general reaction produced in these animals The difficulty lies in appreciating the degree of local reaction

Fraser has found that the ideal situation in which to demonstrate such is the synovial membrane and more especially the synovial membrane of the knee joint of the rabbit By the degree of reaction, clinical and pathologic consequent on inoculation of the joint with a small quantity of bacillary emulsion he can differentiate between the human and the bovine types of tubercle bacilli The test is best demonstrated when an emulsion of the bacilli is injected into the part, but it may be carried out with pus or other pathogenic fluid it is essential, however, that no mixed infection be present The sequelae are distinct If the human bacillus is introduced there are few resulting changes the synovial membrane becomes slightly thickened, [illegible] is [illegible] excess of fluid in the joint, there is no [illegible] no joint the animal continues to [illegible] onsta the joint is examined [illegible] is to be a chronic synovial tubercle It is rare to find any degree of disease in the bones or articular cartilages or throughout the body When, on the other hand, the bovine bacillus is injected, the changes are rapid and acute About ten days after inoculation the animal becomes crippled, the joint becomes swollen and painful, the limb takes up a permanently flexed position, there is a progressive and continuous loss of weight Examination of the joint three to four weeks after inoculation shows the presence of acute synovial tubercle, the interior of the joint is full of caseous debris, the articular cartilages are eroded, there are foci in the neighboring bones and throughout the bod the lungs, spleen and kidneys are diseased The results of fifteen applications of the test are given

21 *Case in Which Torsion of a Hydatid of Morgagni During Pregnancy Without Torsion of Tube or Ovary, Caused Urgent Symptoms H R. Andrews

17 **Pseudomyxoma Peritonei**—Wilson has met with six typical cases of pseudomyxoma of the peritoneum To the end of 1911 he had operated on 331 patients with tumors of the ovary, among which were included 144 glandular pseudomucinous cysts In addition to the six cases of typical pseudomyxoma there have been among the 144 glandular cysts five others in which the contents have been gelatinous, although there has been no extensive effusion into the peritoneal cavity There was a marked difference from the class of patient in whom pseudomyxomatous peritonitis was found In most of the cases a certain quantity usually small, of free soapy exudation was present in the peritoneum, although no rupture or perforation of the cyst could be made out One of the cases is of peculiar interest, in that after removal of a right sided cyst, a second one grew in the left ovary to the weight of three pounds within five months, the left ovary had been observed at the first operation to be shriveled and senile in appearance The second cyst had burst, discharging a large quantity of mucoid fluid into the peritoneal cavity Both cysts were proved by the microscope to be simple glandular in structure This case was further of interest in that the patient had a fibromyoma and later developed carcinoma of the body of the uterus, of which the first symptom appeared within a year of the second ovariotomy, the patient dying about six years later The removal of the two ovaries caused regression of the fibroid, but did not prevent the subsequent malignant development in the uterus an important condemnation of the operation of double oöphorectomy for uterine fibroid

21 **Torsion of Hydatid of Morgagni.**—Tenderness just above and internal to the right anterior superior spine, pain and abdomen distention were the subjective symptoms in Andrew's case On opening the abdomen and exploring the right iliac fossa a small purple body came into view, which was at first thought to be a gangrenous appendix, but was found to be attached to the fimbriated extremity of the right fallopian tube It was about 2 inches long, ¾ of an inch thick and was constricted in the middle of its length It had the appearance of being some soft structure which had become deeply congested and then become practically solid as the result of thrombosis The tube ovary and appendix were healthy and normal The small purple body was removed after its attachment to the fimbriated extremity of the fallopian tube had been ligatured with catgut Nothing abnormal was found in the abdomen except that the uterine wall appeared to be very thin Under the microscope the piece of tissue was found to consist of a thin walled cyst with some lymph on its surface the interior filled up with blood-clot It was apparently a twisted hydatid of Morgagni, which could not have been larger than a small grape before torsion occurred

30 Dangers of Electricity from Clinical Forensic and Hygienic Points of View S Jellinek

22 **Pulmonary Tuberculosis**—In Powell's opinion consumptives on the whole have a much better circulation than they are given credit for, their hearts are relatively good, and a low blood pressure in them is mainly attributable to depressed cardiac function from excessive absorption of bacterial products It is very rare, even in acute cases, to meet with anything approaching the heart failure so often observed in enteric fever or diphtheria, although it may be witnessed after excessive doses of tuberculin In some cases of advanced but quiescent phthisis one meets with great irritability of the heart, with attacks of palpitation or disturbed action easily provoked by exertion, emotion, or dyspepsia, disturbances attended with great distress, sometimes with almost anginal suffering These, Powell says, are cases of one sided disease, usually the left side, in which the lung has become extremely damaged, with considerable cavitation, and has then in the healing process become fibroid and contracted, with dense thickening of the pleura The margin of the lung recedes from the surface of the heart, leaving the pericardium exposed directly beneath the flattened chest wall The chest wall is drawn in, the diaphragm drawn up, the heart, displaced to the left and upward, is closely surrounded on three sides by dense unyielding structures, while the opposite healthy lung is compensatorily enlarged and extends beyond the median line In right sided cases the heart assumes a more vertical position than natural, and is drawn to the right and upwards The heart is thus cramped on all sides in a restricted chamber with rigid parietes, instead of being surrounded by resilient structures whose peripheral influence is aspiratory to its cavities

The marginal zone surrounding the tuberculous caseous center of a tubercle contains tubercle bacilli which are active or sluggish according to the activity of the disease In chronic and quiescent cases they are still there, secreting toxins in a more or less languid manner, and an area of bacillary infiltration surrounding each focus may thus be regarded as charged with stagnant bacterial products which may not get at all into the general circulation, or so gradually and in such small quantities as to cause little or no constitutional disturbance But if in such patients one replaces quietude by activity, or moderate activity by harder labor, two things are accomplished (1) the circulatory activity and blood pressure in these perifocal zones is raised, hastening the blood-currents and the lymph streams, and so bring about increased absorption of the bacillary products and (2) increased disturbance in these areas is further caused by increased movement of the lungs from the hurried breathing It is by these mechanisms combined, but principally the vascular disturbance, that auto inoculation is brought about in tuberculosis and it was after this fashion that Paterson explained what he had previously found by careful observation, that by graduated labor in the sanatorium at Frimley he could bring about certain regulated degrees of auto inoculation, and so obtain gradual immunity in tuberculosis by progressive stimulation of phagocytic action and of other agencies antagonistic to the bacillus

29 **Jejunostomy in Chronic Gastric Ulcer**—The following are the steps of the procedure carried out by Tatlow The stomach is clamped as in the ordinary operation, a loop of 18 inches of jejunum is then picked up and an anterior vertical anastomosis performed. The proximal loop of jejunum is then divided near the anastomosis and implanted into the portion of the jejunum leaving the gastro-enterostomy, the distal cut end near the anastomosis being first closed, thus completing

the modified anterior gastro enterostomy in Y The loop of jejunum coming from the duodeno jejunal flexure to form one limb of the Y is now taken, and at a point two or three inches above the Y, on the side of bowel remote from the mesentery, a small longitudinal incision is made into the lumen of the gut, and a No 14 rubber catheter is introduced. This is fixed in position by a 000 catgut suture, taking in all the coats of the bowel and the catheter, which is then passed well down into the jejunum beyond the anastomosis Then a series of interrupted Pagenstecher sutures is used so as to enfold the catheter in a trough of jejunum as in a Witzel gastrostomy, care being taken not to stenose the anastomosis The line of suture is then fixed to the anterior abdominal wall by a single stitch at each end, and the abdominal wound is closed tightly round the catheter, which projects about 5 or 6 inches

31 *Catarrhal Jaundice Sporadic and Epidemic and Its Relation to Acute Yellow Atrophy of Liver E A Cockayne
32 *Action of Diastase in Diabetes Mellitus O T Williams and P M Powell
33 *Action of Vagus on Human Heart W T Ritchie
34 *Investigations on Gastric Juice in Malignant Diseases of Stomach and Duodenum S B Schryver and C Singer
35 *Influence of High Temperature on Protein Metabolism with *Reference to Fever G Graham and E P Poulton*

31 **Catarrhal Jaundice, Sporadic and Epidemic**—Most epidemics of jaundice, in which the possibility of yellow fever, relapsing fever, and malaria have been excluded, according to Cockayne, are due to infectious jaundice or epidemic catarrhal jaundice Infectious jaundice or Weil's disease is in all probability due to the ingestion of contaminated water or food, but may be due to some biting insect Epidemic catarrhal jaundice is air borne Epidemic catarrhal jaundice is much the commoner disease and is of almost world wide distribution, infectious jaundice is met with chiefly round the Mediterranean Sea, and does not extend to the British Isles Simple catarrhal jaundice, usually attributed to gastro duodenal catarrh, of varying origin, is the sporadic or endemic form of epidemic catarrhal jaundice, except in a comparatively small number of cases Acute yellow atrophy of the liver in the great majority of instances is due to the same organism acting on a liver weakened by some temporary strain, such as pregnancy, or having some inherent weakness A similar condition may be produced by syphilis, infectious jaundice, and other infections, but much less often Sporadic and epidemic catarrhal jaundice and acute yellow atrophy of the liver are due in the great majority of cases to the same cause, a specific organism of unknown nature

32 **Action of Diastase in Diabetes Mellitus.**—In the prolonged daily study of cases of diabetes treated with diastase Williams and Powell have been unable to observe any beneficial effects which could be attributed to it In cases which responded markedly to a course of oatmeal given as advocated by von Noorden, no such effect can be obtained by any preparation of diastase they used If there is any specific body in oatmeal which has an effect on carbohydrate metabolism, they are convinced that it is not a diastase ferment.

33 **Action of Vagus on Human Heart**—The action of the vagi on the human heart, Ritchie says, is closely comparable to that of the vagi on the heart of other mammals Compression of the right vagus may depress the rate and strength of the auricular beats, may prolong auricular systole, and may depress the conductivity of the auriculo ventricular bundle system The inhibitory effects of the vagus on the human auricles ensue gradually, and usually pass off gradually while the compression is still being maintained Compression of the right vagus has not depressed the excitability of the human auricular muscle when in fibrillar contraction or in flutter Depression of conductivity is probably an important factor in the production of fibrillation in the human heart In three cases of complete auriculo ventricular dissociation the vagi had no apparent influence on the ventricles In hearts with a normal rhythm and good conductivity in the auriculo ventricular bundle system, vagus compression may depress the rate and contractility of the ventricles, and less frequently may prolong the duration of ventricular systole The depression of ventricular rate is usually proportionate to the degree of auricular retardation In some instances the auricles escape from vagus inhibition before the ventricles, in others ventricular standstill may perhaps terminate by the occurrence of idioventricular contractions Extra systoles may occur during the escape of the heart from vagus inhibition The inhibitory effects of left vagus compression are as a rule less effective than those of right vagus compression, and the latter are almost uniformly the reverse of those induced by atropin

34 **Gastric Juice in Malignant and Non Malignant Diseases**—The authors found that in about 6½ per cent of cases of grave gastric disorder a ferment is present in the gastric juice capable of hydrolysing Witte's peptone This abnormal ferment is of unknown origin Apparently, however, it is derived neither from the duodenal secretion nor from the saliva, but from the stomach itself It has been detected only in cases with severe dyspeptic symptoms The gastric juices in which the ferment has been detected have been uniformly characterized by their poor hydrochloric acid content and low or absent peptic power In most of the cases, moreover, an extremely low gastric secretory power has been suggested by the small amount of chlorids present The abnormal ferment is neither peculiar to nor characteristic of gastric carcinoma In the majority of cases in which carcinoma was undoubtedly present the peptolytic ferment was absent The commonest condition associated with the ferment appears to be gastric dilatation with atrophy of the walls of the stomach and thinning of the mucous membrane This condition was present in at least seven of thirteen cases and in two that came to post mortem

35 **Influence of Temperature on Protein Metabolism**—A rise of body temperature to 104 3 F (40 2 C) did not, in the authors' experiments, by itself cause any breakdown of the proteins of the body If a diet of very high calorie value is taken, which contains a large excess of carbohydrate but a minimal quantity of protein, non nitrogenous substances supply the whole of the increased energy production set up by the high temperature If a diet of ample caloric value is taken, which contains practically no carbohydrates but a large excess of protein, the fat metabolism is increased, but it is probable that the protein metabolism also takes a small share in the increased energy production set up by the high temperature If a diet of insufficient calorie value is taken, which contains practically no carbohydrates but a fair amount of protein, the fat metabolism is probably greatly increased, but the protein *metabolism takes no share in the increased energy production* set up by the high temperature

44 *The Thymus in Exophthalmic Goiter (Le thymus des basedowiens) C Lenormant

44 **The Thymus in Exophthalmic Goiter**—Lenormant does not agree with those who regard hypertrophy of the thymus as in itself a special danger in exophthalmic goiter The thymus is frequently unduly large in all forms of exophthalmic goiter, but this is not a constant occurrence When hypertrophy of the thymus is associated with hypoplasia of the adrenals, the resulting instability of the cardiovascular system may be a dangerous feature of the clinical picture The general principles for operative treatment of exophthalmic goiter need not be modified on discovery of hypertrophy of the thymus The thymus is of far less importance than the thyroid from every point of view in exophthalmic goiter

58 Causes of Recurrence After Operative Treatment of Inguinal Hernia (Ursachen der Recidive nach Radicaloperation des *Leistenbruches) E Polya*

53 **Resection of Cancerous Stomach**—Kelling has long been preaching that the experiences to date show that infection of the tissues around from the infectious contents of the cancerous stomach is by far the most important factor in development of complications afterward whether they take the form of pneumonia, sepsis, peritonitis or tearing out of the sutures Progress therefore must be along the lines of preventing this operative infection He refrains from taking any suture in the mucosa and summarizes seventy two cases in which he applied the technic he advocates Eleven patients succumbed to the results of the operative infection and in two thirds of these the stomach wall proved to be too friable to hold the button In most of these infectious cases the cancer was unusually high in the fundus and the whole stomach high and inaccessible behind the ribs so that compresses did not work well The unusual friability of the stomach walls is probably the result of arteriosclerosis, and he is inclined to regard this as a predisposing factor for gastric cancer In the four cases of fatal infection after a clean operation, the probable source for it was in some adjacent lymph nodes sheltering virulent bacteria, and this possibility should be borne in mind in debating whether to remove them or not About 42 per cent of the patients operated on before 1910 have developed recurrence, but fourteen are in good health for two or more years Small carcinomas developing in a callous ulcer offer the best prospects for a permanent cure, but the ultimate outcome depends after all on the patient's resisting powers He has found that conditions guarantee better nourishment when the gastroenterostomy is supplemented by an entero anastomosis, as he describes in detail He does not approve of operating in two sittings unless the patient is too weak to stand the resection at once

55 **Treatment of Elephantiasis**—Rosanow reports a case in which he restored the patient to active life by a combination and modification of Lanz and Oppel's methods for diverting the course of the lymph by anastomosis between the superficial and deep lymphatics The photographs show the extreme improvement Diamond shaped patches of skin, 15 or 11 cm across, were cut out of the thigh and calf The subcutaneous tissue and aponeurosis were cut across on the short diameter of the diamond and then cut along one side line down to the muscle This produced two triangular flaps, each was turned over and pushed into the space below between the layers of the muscle separated for the purpose with a blunt instrument The flaps were held with a few catgut stitches in the muscles and periosteum The skin was drawn together and sutured along the long diameter of the diamond, thus exerting compression on the lymphatics below The results surpassed all anticipations

57 **Operative Treatment of Ankylosis of the Knee, Etc**—Sumita gives a long report of the experimental research on which Payr's operative treatment is based The principle of interposing a pedunculated flap of soft tissue can be applied not only in ankylosis of the jaws and elbow but also of the knee, restoring function in a manner unattainable by any other means The interposed flaps soon undergo a fibrous change and grow larger and develop into a kind of bursa which permits the joint to be used naturally Payr devotes seventy four pages and forty one illustrations to his experiences in this line He does not attempt the operation unless the patient is young, healthy and strong, with the extensor muscle apparatus still capable of some functioning, and the patient's will power guarantees active cooperation and he can spare the time necessary for the after treatment He has applied the method to three young women and a girl of 12 and to seven young men and one boy of 11 The ankylosis was of tuberculous or gonorrheal origin in two cases each In three cases a free auto flap of soft tissue was interposed, in the others a large flap from the fascia lata above was drawn down to hold the end of the femur in its loop The outcome was extremely satisfactory in eight cases and conditions will probably improve in all as time passes The interval since has been less than a year in all but two

65 Suture of Blood Vessels (Zur Technik der Gefässnaht) R Eden

59 **Sterilization of the Mucosa During Operations Exposing It**—Hoffmann refers particularly to rapid sterilization of the mucous membrane during operations on the stomach or intestines, and reports research on dogs which has demonstrated that a 5 per cent alcoholic solution of thymol is effectual in rapid sterilization of the skin and mucous membranes wherever

exposed After wiping the surface of the mucosa with a dry sponge as it is exposed in the stump of the stomach or intestine below where it is being held by a clamp, he dabs the mucosa with the 5 per cent thymol spirits, repeating the procedure with a second sponge after a few seconds This does not irritate the tissues while it practically sterilizes the mucosa, materially reducing the number of germs He warns against letting the thymol come unnecessarily in contact with the serosa as liable to invite adhesions, warning further that thymol irritates and entails necrosis when it is left too long in contact with living tissue, one minute, or two minutes at most, seemed to be the limit in his experiments on dogs With contact longer than this, the tissues always showed microscopic or visible signs of injury In applying the method to man, he never allows the thymol in contact for more than a few seconds He has been using this disinfectant in all kinds of operations during the last eighteen months and always with highly satisfactory results

61 **Epidermoid Cysts of Unusual Location.**—Simon has compiled from the records twenty five cases of epidermoid tumors on the toes, penis, arm, leg, ear, scalp, over the clavicle or on the buttocks or abdomen The cysts are liable to rupture and become infected as in the personal case described.

79 Training of Nurses for Sick Infants (Ausbildung von Säuglingskrankenpflegerinnen nach einheitlichen Grundsätzen) J Ibrahim

69 **Modern Surgery**—Sonnenburg remarks that the surgeon must no longer place his entire reliance on the knife but must utilize every possible means to aid the organism in its struggle against disease He must strive to avert all the injurious influence caused by and on account of the operation, to prevent the natural protective forces from becoming exhausted and the resistance enfeebled Complex disease processes can never be cured by exclusively operative measures The surgeons have receded a few steps in the last few years they no longer trephine idiots, etc, and only occasionally an epileptic, and they no longer expect to cure exophthalmic goiter by an operation on the sympathetic alone In ileus the mechanical factors have been too much regarded in the past and the functioning of the intestines too little Tuberculous processes in joints are operated on less and less

70 **Pernicious Anemia**—Brieger calls attention to the discovery of the frequently high antitrypsin content in the serum of persons with cancer and the remarkable effect of pancreatin in bringing the antitrypsin titer down to the normal figure, while the general health improved These and other experiences have suggested that there is a connection between the condition in regard to immunity and the condition in regard to protective ferments He found that diphtheria antitoxin contains increasing amounts of antitrypsin with increasing immunizing power—all of which confirms the importance of an unusually high antiferment content in exhausting diseases and the possibility of restoring conditions in this respect approximately to normal by pancreatin He has applied these principles in treatment of pernicious anemia, and reports three cases in which he gave Fowler's solution, by the usual dosage after meals and pancreatin before the meals The rapid improvement in all three patients under this combined treatment was remarkable neither alone proved effectual A permanent cure was not realized two of the patients dying later after they had given up treatment, but the third has been under supervision for three years, treatment is resumed whenever the blood findings show recurrence of alarming symptoms A striking feature of the cases was the rapid drop of the antitrypsin content of the blood to within the normal range He has had similar improvement, although of brief duration, in several cases of cancer He is now investigating to determine whether pancreatin will not prove a useful adjuvant in other affections It is possible that pancreatin may have catalytic powers in addition to its effect on the digestion and assimilation

72 **The Blood Test for Pregnancy**—Abderhalden here reviews the results of his research which were described in THE JOURNAL, Sept 14, 1912, p 881, and December 7, p 2073 The dialysis method and the optic method speedily distinguish the serum from gravid and non gravid women and animals Some of the experiences suggest that the placenta in different species of animals contains biologically identical or closely allied protective enzymes or ferments The methods described seem to open a field for research in several branches of pathology When the blood serum is mixed with the peptone derived from a placenta and the rotation of the plane of polarized light is determined, by this optic method it is possible to differentiate the serum from the gravid and the non gravid. In all his experience he never obtained a negative result with serum from pregnant women or animals He found that the findings became positive when placenta material was injected subcutaneously or intravenously even into a male The dialysis method is even simpler The placenta tissue is mixed with serum in a dialyzing tube and is suspended in a jar containing 20 c c of distilled water After sixteen hours' incubation, 10 c c of the dialysate is transferred to a test tube and tested for the products of proteolysis A positive color reaction shows that the serum has digested the placenta tissue Positive findings show that the serum comes from a person with a placenta but this does not tell whether there is a living fetus present or not If the reaction is positive and there has been recent uterine hemorrhage, even in the absence of other signs of pregnancy, an abortion is suggested. The 300 cases tested to date have not yet fully settled whether the reaction is specific for pregnancy alone The reaction generally grows weaker towards the end of the pregnancy and increases again during the puerperium It has not failed to date in any *instance of pregnancy* He urges clinicians in general to test the method and also to determine the action of the undiluted serum in different conditions on the plane of polarized light The serum can be utilized afterward for other tests In diabetes it might pro[illegible] [illegible]eful [illegible]t the rotatory action of the serum on diff[illegible] [illegible] that the rotatory action of the serum of [illegible] [illegible]ffered from that of the mother's [illegible] [illegible] cent [illegible]

examined displayed the same action on polarized light as the mother's serum This confirms the biologic independence of the maternal and fetal blood

74 **Hypermotility of the Stomach with Duodenal Ulcer**—Kreuzfuchs found that the motor functioning of the stomach differed according as the stomach was empty or not before the test bismuth was given Achylia and incipient cancer of the pylorus may present a radioscopic picture exactly like that of duodenal ulcer, so that the stomach content should be tested at the same time to avoid error Hyperchlorhydria plus the duodenal gastric motility testify strongly to duodenal ulcer

75 **Origin and Diagnosis of Pellagra**—Raubitschek presents a further array of arguments to sustain his view that pellagra is the result of a restricted diet supplemented by the injurious action of the sunlight It is thus a dietetic photodynamic disease, and in prophylaxis and treatment neither of these factors should be neglected

76 **Indicator Method Applied to Study of the Urine**—The changes in tint with the varying thickness of the fluid to be examined form the basis of Friedenthal's indicator method of studying various fluids The technic has been further elaborated and applied to the study of the urine, with considerable simplification of the original method It is commended as simple and practical, while the findings are said to be reliable.

81 **Duodenal Ulcer in Infancy**—In recent years duodenal ulcer has been reported much more frequently in proportion to gastric ulcer In infants a considerable number of cases has been reported Entz reported eleven cases in 364 autopsies at the Budapest Children's Hospital in 1908 The ages were from six weeks to six months It is seldom diagnosed during life Flesch gives the history of a case diagnosed during life from the profound anemia and bloody stools The child had been fed first milk and gruel, then the milk had been given up entirely The lack of salts and the inanition caused by the improper feeding led to injury and finally to autodigestion of the duodenal mucous membrane

84 **Henoch's Purpura**—Gara reports two cases from his own experience and cites from the literature seventeen, all in children The characteristic symptoms are the appearance of purpuric spots, pains in the joints, gastric and intestinal disturbances, with colic and vomiting He concludes from the necropsy findings that purpura abdominalis is frequently associated with intussusception, whether as cause or effect is still undetermined

102 *Minor Practical Points (Praktische Winke) R Mewerth

94 **Early Diagnosis of Pulmonary Tuberculosis**—Hoffmann is in charge of the observation station with eighteen beds to which candidates for the public sanatoriums are referred for selection of the cases promising recovery under institutional care During the last year 500 patients were thus examined The outcome of the cases is compared with the presumptive diagnosis made in the observation station He has found percussion of the apices of little use for detection of incipient tuberculosis, as also the finer modifications in the breathing sounds To avoid disturbing muscle sounds, he gives the patient the evening before 1 gm sodium iodid and a sedative, sometimes repeating the sedative early the next morning The skin and eye tuberculin tests are useless in adults, but radiography is of the greatest help In many cases in which the clinical examination was dubious, the radiograms settled the question for or against tuberculosis Of his 700 roentgen ray plates, 200 were examined for disease on both sides, and it was found bilateral in 114, in all some connection with the hilus was evident The foci are not always at the apex, but may spread sideways from the hilus in triangular shape. This connection with the hilus is an important aid in dubious cases Radiography was of the least use in cases with initial hemoptysis Other cases of tuberculosis in the family were known in only 18 per cent of the total material Pains in the back, chest, side, abdomen or sacral region were more common than cough in the patients examined Among those who proved not to be tuberculous—although sent in with this diagnosis—were some with diabetes, nephritis, tapeworm or cervical ribs, and 15 per cent of them had acute bronchitis, others were debilitated from defective food or alcoholism His experiences show that it is impossible to diagnose or exclude incipient pulmonary tuberculosis by office examination. Photograph records of the roentgen ray findings are indispensable, he thinks, and reexamination after two and four months on a presumptive negative diagnosis Another point emphasized by his experience is that pulmonary tuberculosis often reaches an advanced stage without the patient having ever consulted a physician

95 **Gynecology and Psychiatry**—Peretti protests energetically against Bossi's demand that women with mental disease should be sent first to a gynecologic clinic and gynecologic morbid conditions corrected before being taken to the insane asylum He presents a number of arguments to show the inadvisability of such a measure He has had a number of patients in the institution in his charge in which the mental disease was not modified by thorough gynecologic treatment

98 **The Distant Reaction of Degeneration**—Forli calls attention anew to Ghilarducci's distant reaction, that is, placing the electrodes at a distance from the muscle to be tested, in such a way that the muscle lies between the poles A distinct contraction can be felt in the muscle when the current is closed He reports three cases to show the value of this reaction, both in diagnosis and prognosis Hope need not be given up as long as this distant reaction occurs, even when all other electric tests give a negative response

99 **Treatment of Flat-Foot**—Stephan uses a kind of stilt to bring the bones of the foot into proper position It differs from ordinary stilts only in that the foot piece rests on the floor, and slopes upward to its outer edge, so that the scaphoid bone is raised, thus restoring the arch of the foot The foot is placed in the stilt with its outer edge against the shaft He has his patients walk with the stilt once or twice a day in their room until the bones stay in the proper position Children with flat foot find these stilts a pleasant diversion

102 **Some Improvised Helps**—Mewerth calls attention to the coffee pot as useful for an improvised inhalation apparatus The patient takes the spout in his mouth ——A handy thermophor can be made of a stout linen bag holding two pounds of

oats or bran, heating the bag in the oven.——In case of a boil in the axilla or on the arm or a felon, the arm can be comfortably supported as the patient reclines, by placing a board under the arm, the end under the axilla resting on the bed, the other end held up at an angle of 45 degrees by a rope fastened to a nail in the wall at the head of the bed.——In suturing the perineum after delivery, he is careful not to cut the threads but to leave the ends long and tie them together in a bunch about 5 cm. from the skin before cutting the ends. By this means one is sure of not overlooking any of the threads later.

105 *Enucleation of Uterine Myomas. P. Schöpp.
106 Changes in Fallopian Tube During Pregnancy. (Schwangerschaftsveränderungen der Tube.) J. Wallart.

104. Stroganoff's Prophylactic Treatment for Eclampsia.—As THE JOURNAL has repeatedly mentioned, the essential feature of Stroganoff's treatment is the long continued administration of morphin and chloral hydrate and the absolute avoidance of external irritation by quiet, darkening of the room, and in some cases chloroform, with delivery by version or forceps in extreme cases. (For literature on the subject see THE JOURNAL, Nov. 30, 1912, p. 1992.) His dosage may be summarized as follows: immediately 0.01 or 0.02 gm. morphin, one hour later, 1.5 or 2.5 gm. chloral hydrate, the third hour, 0.015 gm. morphin, the seventh hour, 2 gm. chloral, and the thirteenth and twenty-first hour, 1.5 gm. chloral. Holste has treated fifteen women satisfactorily by Stroganoff's method with some modifications. He does not hesitate to induce labor more freely by means of bags, and he does not continue the medication after delivery for fear of secondary lung complications. He discontinues the drugs as soon as marked improvement is noted. He advocates the giving of morphin at the first sign of prodromal symptoms, and thinks that convulsions may often be avoided in this way. He mentions as a possibility in treatment, the administration of serum from a pregnant woman. This serotherapy has been tried in a few cases. On the whole he regards Stroganoff's treatment as preferable to immediate delivery by vaginal or cesarean section, although the method is far from ideal.

105. Enucleation of Myomas.—On the basis of sixty operations performed by him, Schöpp discusses the value of enucleating myomas as compared with the radical removal of the uterus. The conservative operation presents greater technical difficulties than the radical one, yet the mortality was only 5 per cent., not greater than is common in hysterectomies. The great advantage of the enucleation technic is that it leaves the patient capable of bearing children, 10 per cent. of his patients bore children after the operation. In two cases the operation was performed on a gravid uterus with happy results for mother and child. The point commonly urged against enucleation is the danger of recurrence. In 70 per cent. of his cases there was no sign of recurrence. Moreover, at the present time roentgenotherapy offers a valuable adjuvant measure in the treatment of small myomatous nodules which may have escaped detection at the operation.

116 When to Drain the Common Bile Duct. (Indikationen für die Hepatikusdrainage.) B. Riedel.
117 Excretion of Urea Through the Skin in Nephritis. Portig.

108. Improved Technic for the Antitrypsin Test.—The original technic for the test of the action of the proteolytic ferments was with a Loeffler plate to which loopfuls of the solution of the ferment were transferred. Kantorowicz has improved on this by using sheets of gelatin instead of the plate, the gelatin sheets keep indefinitely and the record is thus permanent. He uses fine gelatin, such as comes for culture mediums, dissolving 6 gm. in 100 c.c. of physiologic salt solution stained deep red with fuchsin and rendered sterile by addition of 0.5 gm. of phenol. He pours 10 c.c. into rectangular shallow dishes. They can be made out of old photograph plates by running a strip of gelatin around the edge to form a wall, pouring the gelatine inside this wall as it hardens. The normal serum digests a circular patch of the gelatine, the presence of the antitrypsin ferment is shown by the smallness of the resulting hole. After twenty-four hours at 22 C., a little lake is seen where each drop has been deposited. The sheet of gelatine is then rinsed in water and the holes in the gelatine look as if punched out with a circular punch, as he shows by two illustrations. The hard sheets of gelatine can be kept indefinitely.

112. Transplantation of Bone Marrow.—Chiari reports successful transplantation into the spleen of a rabbit of a small lump of bone marrow. It had retained its vitality and was found to have increased materially in size when the animal was killed five months later.

113. Necessity for Prophylactic Appendectomy.—Hörrmann insists on the advantages of removing the appendix when the abdomen is opened for a gynecologic operation, reporting instances in which the macroscopically sound appendix was found diseased and a tendency to cancer in some. Of course, after the age of 60 he would not remove the appendix without special cause, nor with cancer, nor in emergency operations.

122 *Foreign Bodies in Bladder of Girl Infants. (Ueber Harnblasenerkrankungen bei kleinen Mädchen durch bisher nicht beobachtete Fremdkörper.) H. Abels.

119. Serodiagnosis of Cancer.—The findings on examination of 250 serums from different sources are tabulated. In seventy-four cases the diagnosis on the basis of the serum findings was confirmed by necropsy or histologic findings. In fifty-eight of these all the findings corroborated each other. In sixteen some were contradictory. In 118 cases with only clinical confirmation of the diagnosis there was a contradiction only in seventeen cases. In some of the dubious cases the findings classed as doubtful might really be listed as positive. The table shows that the meiostagmin reaction gave positive findings in 82.8 per cent. of 399 cases of cancer while the reaction was positive only in 9.5 per cent. of 548 persons healthy or with other affections, as reported by eleven research workers. Ascoli obtained a positive reaction in 93 per cent. of his 100 cases. With the Freund-Kaminer technic a positive reaction was obtained in 83 per cent. of fifty-three cases of known cancer and only in 12.5 per cent. of sixteen patients with other affections. Freund and Kaminer comment on the above report that it is suggestive that two patients with tuberculosis and three with gall-stone trouble are in the list of contradictory findings. In one such case in their experience the gall-stone trouble masked a cancer. They warn further that the state of the blood during digestion is liable to interfere with the test for serodiagnosis, the blood should be taken during a fasting period. Another source of possible error is the presence of red corpuscles in the serum, the more limpid the serum the better the findings. [illegible] A little phenol keeps the serum in good condition [illegible] material is thoroughly rinsed with salt solution they found it active for five months They state that by using smaller amounts of serum for the test, it is possible to repeat the procedure several times with a given amount of blood Tests with only a drop or two of serum on the slide have given characteristic results

122 **Bladder Affections of Unusual Origin in Girl Infants**—Abels reports two cases in which severe cystitis in children 9 and 17 months old was explained by discovery of paper and a hair in the bladder, and Blum has recently reported a somewhat similar case in a girl of 4 In the latter case threads from the child's clothing were found in the bladder, and it was learned that she had a habit of pressing her clothes on the urethra to control micturition In the cases of the infants, paper had evidently been rolled up and wound with a hair and introduced like a catheter into the bladder by another person

131 *Anesthesia by Epidural Injections (Hohe und tiefe extradurale Anästhesien) B Strauss

128 **Puerperal Tetanus**—Freund has encountered three cases at intervals of years and is convinced that the infection occurred from the anus through some laceration of the perineum as all other causes seemed to be excluded His experiences teach that women approaching term should be very careful in eating green vegetables and uncooked berries as these are liable to be contaminated with tetanus germs and thus may infect the obstetric wounds through the stools His experience further confirms the value of the traditional practice of giving an active and thorough purge at the beginning of labor and a cleansing enema during the second stage of labor, with careful cleansing afterward He warns further that no obstetric operation should be undertaken without thorough cleansing and sterilization of the skin and protection against infection from the anus He uses for the purpose a large gauze compress pressed between the buttocks fastened with plaster and a towel over the whole firmly fastened in place He thinks that a vaginal douche before the first internal examination and before every obstetric intervention is the best protection against infection from without The alleged harm from changing the chemistry of the vaginal secretions by the douches is far outbalanced by the benefit from mechanically washing out the germs and the material in which the germs find conditions favorable for their development Freund adds further that a prophylactic dose of tetanus antitoxin should be given in every case of criminal abortion in which a wooden instrument was used or its use suspected If the tetanus has developed, antitoxin treatment has little prospect of success unless the bacilli are in evidence In his three cases he was not able to find the bacilli as the period of incubation had been so long before the tetanus developed In the first case a healthy woman convalescing from a well managed childbirth developed fatal tetanus, the first symptoms appearing the ninth day and no source for the infection could be discovered except the possible infection from the stools He adds a case of tetanus from infection of the umbilicus which he traced to the custom of dressing the umbilicus with the sawdust resulting from the boring of the wood beetle in the banisters—this *Holzpulver* being a favorite family remedy in some districts of Germany Freund refers to the Prague epidemic of puerperal tetanus in 1898 in which twenty-eight women died in the course of eighteen months

131 **Epidural Anesthesia**—Strauss reviews his experiences with eighty cases in which operations were performed under extradural sacral injection of the anesthetic The chief advantage of the method is the total absence of complications on the part of the air passages No headache followed the injections, such as is frequent with spinal anesthesia He tabulates the details of the various cases but adds at a later date the case of a woman of 27 who succumbed during an operation for uterine cancer six weeks after a childbirth and necropsy revealed chronic nephritis tuberculosis of the kidney and metastasis in the liver which he thinks is sufficient to explain the fatality without incriminating the method of anesthesia Otherwise he had no by effects except, in a few cases, transient pallor and acceleration of the pulse

DIAGNOSTIC PITFALLS IDENTIFIED DURING A STUDY OF THREE THOUSAND AUTOPSIES *

RICHARD C CABOT, MD
BOSTON

I wish in this paper to make three points 1 A goodly number of "classic" time-honored mistakes in diagnosis are familiar to all experienced physicians because we make them again and again Some of these we can avoid, others are almost inevitable, but all should be borne in mind and marked on medical maps by a danger-signal of some kind "In this vicinity look out for hidden rocks," or "Dangerous turn here, run slow" I shall enumerate some of these danger points presently

2 Some common diseases are relatively inaccessible to diagnosis, no matter how carefully we are on the watch for them From the study of 3,000 autopsies, I have begun to work out a percentage or ratio of accessibility for the commoner diseases (shown in the accompanying chart)

3 Besides the classic and well-known pitfalls there are some less familiar to the profession and needing all the more, therefore, to be marked "dangerous"

FREQUENT AND WELL RECOGNIZED PITFALLS

I shall first enumerate without discussion some of the commoner mistakes

"Acute gastritis" is a rare disease in adults As a rule appendicitis or gall-stones is the correct diagnosis

"Chronic indigestion" is usually a mistaken diagnosis, the actual condition being peptic ulcer, pulmonary tuberculosis, constipation or cancer of the colon

"Bronchitis" usually proves to be phthisis, bronchiectasis or bronchopneumonia at autopsy or in the outcome

"Asthma" beginning after middle life is usually symptomatic of cardiac or renal disease

"Unresolved pneumonia" is frequently a mistaken diagnosis, the real disease being interlobar empyema

"Malaria" is often given as the diagnosis in cases of phthisis, hepatic syphilis, hepatic abscess and urinary infections

"Typhoid fever" in a *patient's history may mean* tuberculosis or latent sepsis (septic endocarditis, suppurative nephritis, etc)

"Rheumatism" has sometimes turned out in my experience to mean aortic aneurysm, cancer of the pleura, tabes dorsalis, osteomyelitis, spondylitis deformans, bone-tuberculosis, syphilitic periostitis, lead-poisoning, morphin habit, alcoholic neuritis, trichiniasis and gonorrheal infection "Rheumatism" is one of the most dangerous of all diagnoses to the conscientious physician

"Cystitis" is usually a symptom, not a disease It points to disease below the bladder (stricture, obstructing prostate, etc), or above it (renal tuberculosis and other renal infections) as its cause

"Hemorrhoids" often mask cancer of the rectum

"Neurasthenia" The real disease almost always shows itself in youth on the basis of congenital tendencies, though like tuberculosis it may be roused into active progress by any prolonged strain, mental or physical When it appears after middle age it is almost always a symptom of organic disease such as dementia paralytica, chronic nephritis, arteriosclerosis, myxedema, hyperthyroidism or phthisis

The incipient stages of the disease mentioned in the last sentence are rarely recognized The same is true of gastric ulcer, pernicious anemia, leukemia, cirrhosis of the liver, congenital renal cysts, renal tuberculosis and many other diseases

All this is trite and obvious, but I mention it to *avoid the reproach of ignoring it*

As one looks at the accompanying chart of diagnoses one naturally asks Whose success or failure does this represent? Where Smith and Jones have failed, could you and I have done better? I doubt it The study of the details in these cases before and after death convinces me that, for the present and under the present limitations of diagnostic method, few of the mistakes tabulated above could have been avoided The table represents the success-and-failure ratio of certain methods rather than of certain men Admitting that the man behind the gun (or the method) makes a vast difference, I do not believe that these figures depend to any considerable degree on the possession or lack of special virtuosity in diagnosis They mirror the methods of an average up-to date American hospital

But the figures are undoubtedly modified by the great difference between terminal lesions (such as acute endocarditis, pericarditis and nephritis) and insidious slowly developing lesions like those of typhoid infection or pernicious anemia In the latter we succeed, in the former we fail frequently

Again, diseases which kill so quickly that the period of observation is very brief and the history often faulty or lacking altogether will always show a large percentage of diagnostic failures Cases of cerebral hemorrhage or coronary occlusion exemplify this

At the successful end of this table I might have inserted (did space permit) pernicious anemia, leukemia, malaria, [illegible] p [illegible] renal c[illegible], dementia paralyti[illegible] and [illegible] eases which are easily recognized as a rule by the routine application of modern diagnostic methods.

---

* Read in the Section on Practice of Medicine of the American Medical Association, at the Sixty-Third Annual Session held at Atlantic City June 1912

At the other and more humiliating end of the scale I could add acute pancreatitis, hemorrhagic pachymeningitis, hypernephroma (in its early stages) and many others.

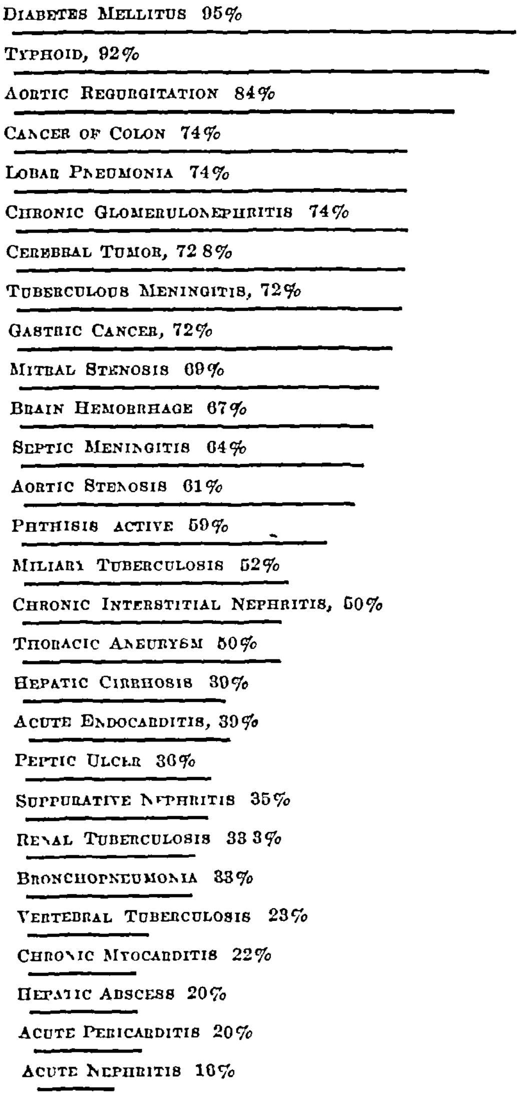
RELATIVELY UNFAMILIAR MISTAKES

VERTEBRAL TUBERCULOSIS

Most physicians believe that Pott's disease of the spine is easily recognized because of the "knuckle" in the spine, the pressure signs, muscular rigidity and secondary abscesses, but the difficulty is precisely in that group of cases which do not show these signs.

PERCENTAGES OF DIAGNOSTIC SUCCESS

TABLE SHOWING GRAPHICALLY THE PERCENTAGE OF CORRECT DIAGNOSES IN VARIOUS DISEASES



Some of the most humiliating yet almost unavoidable failures of my experience have been made in cases which showed post mortem the lesions of Pott's disease. Only four of the seventeen cases that came to autopsy in this series of 3,000 post-mortems were recognized in life. In ten of the thirteen "misses" there is "no blame to be attached to the officials in charge." The diagnosis was not suggested by any of the facts at our disposal. The clinical picture was usually that of an overwhelming infection (miliary) which was called "septicemia from pelvic abscess" (really a psoas abscess) "meningitis," "acute uremia" (two), "septic scrotum," "otitis media with pyemia," "pneumonia" (two) and "septic hand with general sepsis."

In two cases there was a slight kyphos which should have been noticed, but as it had been there for many years without change, it was ignored. In one case there was a gradual, even curve of the whole spine diagnosed by a skilful orthopedic consultant as spondylitis deformans.

The ages of the thirteen patients whose disease was unrecognized were 26, 51, 54, 81, 29, 44, 49, 53, 50, 64, 65, 45, 40. The average is fifty years. In the four recognized cases the ages were 34, 40, 34, 21 (average, 32).

The moral is that we do not look or ask carefully enough for evidence of old vertebral tuberculosis in elderly patients, because we associate the disease with youth.

ACUTE UREMIA

In this series and in private practice outside it I have never found a correct diagnosis of acute uremia. Yet the diagnosis is a very frequent one. Among the diseases wrongly diagnosed as "acute uremia" I have seen two cases of sporadic meningitis (due to Weichselbaum's diplococcus), two of miliary tuberculosis, one of general streptococcus sepsis, three of arteriosclerosis (especially cerebral, kidneys sound), one of hepatic cirrhosis, one of pyelitis and one of bladder cancer.

Most of the wrong diagnoses of acute uremia are made in comatose patients seen for the first time in that condition and with little or no history obtainable. The urine is drawn by catheter and found to be loaded with albumin and casts. The diagnosis follows, regardless of the fact that in practically all comatose patients we find abundance of albumin and casts, no matter what the cause of the coma may be. I will not deny that acute uremia may occur and be recognized post mortem as the cause of death, but in my experience and in the 3,000 autopsies which I have studied, it has never been so. In my experience, uremia is a chronic condition supervening gradually and in association with edema, vomiting, headache and retinitis in relatively young subjects. In these cases no other cause for coma is found post mortem and the kidneys are extensively diseased. The blood-pressure is usually high but may be low. In most of the cases diagnosed as "acute uremia," other well-recognized causes of coma are found post mortem, and the kidneys show no evidence of nephritis.

I have therefore ceased to consider acute uremia in the diagnosis of cases of sudden coma "out of a clear sky" or with only a few days' illness preceding.[1]

CIRRHOSIS OF THE LIVER

That this disease has a long period of latency when diagnosis is impossible, has long been recognized, and most of eighty cases autopsied in the Massachusetts General Hospital series merely corroborate this.

Of the eighty cases, thirty-one were recognized during life, and forty-nine were not recognized. In sixteen of the forty-nine "misses" the amount of interstitial change was but slight at autopsy, but there remain thirty-three cases unrecognized despite a well-marked type of the disease. In three cases the clinical picture was essentially that of apoplexy, though the brain was normal Sudden death (toxemia) is by no means rare in cirrhosis, the fatal coma quickly supervening in apparent perfect health If cirrhosis had been considered as a factor in the differential diagnosis of these cases it is possible that the diminution in liver dulness might have been recognized and the disease identified

---

[1] Puerperal eclampsia is of course often acute but its cause does not reside in the kidney.

Three cases were mistaken for peptic ulcer on account of the profuse hematemesis In time I think it will be recognized that this symptom is of more value in cirrhosis than in peptic ulcer since it occurs in only 20 per cent or less of the ulcers (gastric or duodenal), and in 26 per cent of the cirrhoses[2] Moreover, hematemesis without other symptoms is far more characteristic of cirrhosis than of ulcer, which usually produces pain of a recognizable type and course

In six cases the clinical picture was that of decompensated heart disease I do not see how the cirrhosis could have been recognized, especially as not all the cases were alcoholic The absence of alcoholism by no means excludes "alcoholic cirrhosis"

In three cases gall-stones were also present and caused all the symptoms

Cirrhosis was latent in patients dying from hyperthyroidism, cancer of the prostate, cancer of the rectum, cancer of the cecum, pancreatic cyst, pancreatic cancer, pneumonia after fracture of the femur, cut throat, aortic aneurysm, dementia paralytica, diabetes, hemophilia (no jaundice), and many other diseases

Cases without ascites were rarely recognized in this series, though in some of these non-ascitic cases the "causeless hematemesis" should have suggested the correct diagnosis When ascites was present the disease was mistaken (in two cases) for tuberculous peritonitis (a disease which did not occur simultaneously in this series, though many such cases are on record) The high lymphocyte count not infrequently found in the sediment of cirrhotic ascites helped to mislead us

The terminal event was pneumonia in three cases, general streptococcus peritonitis in two

My chief conclusions from this series are that we have underestimated the frequency of the disease and the difficulty of its recognition, that it must be remembered as a possibility in all cases of sudden "causeless" coma and especially when unexplained hematemesis is the main symptom

CANCER OF THE COLON

Out of forty-three autopsied cases, eleven, or over 25 per cent, were not recognized in life In this group two patients were operated on and even then the cancer was not found Two others had brain-metastases, and all other symptoms (as in miliary tuberculosis) were overshadowed by the cerebral manifestations Two were not recognized as springing from the colon because perforation of a stercoraceous ulcer above the obstruction had led to the formation of a large perienteric exudate so firmly fixed to the surrounding parts that in life a tumor springing from the pelvic bones was suspected In studying the ante-mortem conjectures and post-mortem findings, it is clear that the perforation of stercoraceous ulcers had not been recognized as a frequent complication in cancer of the colon The symptoms of a general peritonitis resulting from such a perforation constituted the first and last act of the clinical drama in one case of this series

In two cases the most prominent symptoms were those of acute renal infection ("pyelitis")

Tumors were rarely felt Most of the correct diagnoses were based merely on symptoms of chronic and increasing obstruction (often with intermissions of perfect health or of diarrhea) in elderly persons The inference that cancer was the cause of this obstruction was made simply because statistics show that cancer is the only common cause of chronic obstruction in elderly people (average age, 59)

A long period of latency (palpable tumor for three years in one case) without symptoms and then a sudden acute obstruction, is a common clinical type of this disease

I conclude therefore that in the diagnosis of cancer of the colon we must be guided chiefly by the evidence of obstruction, without obvious origin, in an elderly person, that we must remember the frequency of perforated stercoraceous ulcer as a prominent clinical feature in many cases, and that complications such as cerebral metastases or urinary infection may overshadow the intestinal symptoms

HEPATIC ABSCESS (NON-AMEBIC)

In thirty autopsies there were six correct diagnoses (20 per cent) In three other cases the diagnosis perhaps should have been made on the evidence available

The clinical picture is one of general septicemia, usually without definite signs pointing to the liver We have learned, however, that fever, chills and leukocytosis following an appendix operation with drainage usually means hepatic abscess Five of the six correct diagnoses were in cases of postappendicular sepsis, one other followed cholecystitis

Occasionally jaundice and an enlargement of the liver, demonstrable in the right back by signs identical with those of a small pleural effusion, give us a hint of where the pus is

Many cases of so-called "toxemic" or "hematogenous" jaundice in sepsis are due in fact to hepatic abscess

Pain and tenderness over the liver were not present in a single case of this series — as would be expected from the post-morten findings The pus was always deep in the substance of the liver, never impinging on the capsule where all the liver's sensitive nerves are distributed

General sepsis after operations involving drainage of the appendix or the gall-bladder, or after an attack of colitis, should always make us suspect hepatic abscess

CANCER OF THE ESOPHAGUS

One of the simplest of diagnoses, one would say offhand, and yet among the twenty cases autopsied in this series four were not recognized in life, and in three others the diagnosis was doubtful

In three of the four "misses" and one other case correctly diagnosed by esophagoscopy, there was no dysphagia whatever In one of these blood was vomited and the clinical diagnosis was "cancer or ulcer of the stomach" In another there were no gastro-intestinal symptoms and no dysphagia The clinical picture was of cardiorenal disease and this was confirmed at autopsy, but the gullet cancer was also obvious and extended into the cardiac end of the stomach It has produced no constriction and no gross hemorrhage Hence it was "silent" and unrec

In a third case

tumor in the neck

cancer, but its

was not suspecte

reasonably have

---

[2] Rolleston Diseases of the Liver p 263.

In the fourth of our "misses" there was dysphagia, but as this was associated with paralysis of the left vocal cord and an *x*-ray shadow interpreted as aneurysm or mediastinal tumor, we were thrown off the track Hoarseness or aphonia (such as occurred here) was present in two other cases and should be remembered as a not uncommon sign of gullet cancer

The percentage of wrong diagnoses in this series would have been larger but for the routine use of the esophagoscope in the later cases Dangerous though this procedure is in any but the most experienced hands, it is yet a necessity for accurate diagnosis of the cause of gullet obstruction in many cases

One case with hematemesis and intermittent (not constant) dysphagia had been considered a functional or spasmodic rather than a cancerous stricture until esophagoscopy revealed its true nature

LATENCY OF ADVANCED PHTHISIS IN DIABETES MELLITUS

Though the frequency of phthisis complicating diabetes is a familiar fact, it is not generally recognized, I think, that there is a peculiar latency and lack of symptoms in this type of tuberculosis In thirty-nine autopsies in cases of diabetes there were nine cases of active tuberculosis and not one of them was recognized in life In one other case tuberculosis was diagnosed but pneumonia (not tuberculosis) was found Most of these patients had no expectoration and slight or no cough — quite a different clinical picture from that usually seen in non-diabetic cases of phthisis in the same stage of the disease

ABSTRACT OF DISCUSSION

Dr Charles G Stockton, Buffalo, N Y Two years ago in St Louis Dr Cabot delivered an address which I think was epoch making in diagnosis in internal medicine I have made it a practice to reread that address each year since then and I commend the practice to my fellows here It is a matter of great importance that one is able to carry out such a study in an institution where the records are so carefully kept and the examinations so well made I should like to inquire, however, why such an inquiry had not been made before Why is it not possible to do the same to day in other institutions similar to the Massachusetts General Hospital? In most hospitals the records are not of a character permitting a review which would give valuable information

If nothing else comes from my remarks I hope that they may stimulate a desire to secure better and more uniform systems of records, so that more certain results may follow summarization If this were done we would have an enormous mass of statistics from which we might make estimations that would be invaluable Think what would follow if the men here present would present their results as these have been presented to day by Dr Cabot Of course this requires the opportunity, and it requires the man as well

What Is Dirt?—It is by hygienic precautions that certain diseases are prevented and the basis of bacteriology is experiment in animals But I should like to quote again from Professor Halliburton on the general questions of serum treatment which has been stigmatized as "messy besides some less elegant criticisms Filth or dirt" he says, "has been well defined as matter in the wrong place Blood on a carpet for example is certainly messy and dirty it ought not to be there But blood or serum in the heart or in the arteries and veins is in its rightful place, and it does its duty of nutrition where it comes into more immediate contact with the tissues—the small tubes we call the capillaries One of these duties is to exert a protective influence on the whole body, by destroying the germs of disease which get into the body in spite of all precautions"
—F M. Sandwith in *Clin Jour*

PATHOLOGIC LESIONS OF THE KIDNEY ASSOCIATED WITH DOUBLE URETERS

REPORT OF CASE OF HYPERNEPHROMA *

A. RAYMOND STEVENS, M D
Adjunct Assistant Attending Genito Urinary Surgeon Bellevue Hospital
NEW YORK

In all branches of medical practice it is a great joy to the physician accurately and minutely to fix the seat of disease Localization of trouble in one kidney with simultaneous exclusion of it from its fellow is such an old story to the urologist that this really clean-cut diagnosis no longer arouses amazement Yet when some fortuitous anatomic or other condition makes possible a closer localization of a pathologic lesion, his enthusiasm is aroused After all, in the apparently simple cases perhaps he is sometimes too sure of himself Anomalies in the excretory apparatus may seriously upset his calculations and at times lead to most disastrous results to the patient My interest in the subject of anomalies has been keenly aroused by the following case

REPORT OF CASE

Patient—A married woman aged 43, entered the Presbyterian Hospital of New York City, Jan. 23, 1912, in the service of Dr Joseph A Blake, to whom I am indebted for the privilege of making this report The patient had pneumonia three years before admission, and had coughed blood one year before, a supravaginal hysterectomy had been done three months before admission

Present Trouble—The patient had attacks of hematuria and pain in the right lumbar region One year before, the patient had felt a sharp non radiating pain in the right lumbar region, lasting several hours The next day very bloody urine was passed. A similar attack occurred six months later, and several more subsequently There had been no frequency of urination and no loss of weight Occasional night sweats and some cough were complained of recently

Examination—The patient was a small, thin woman, perhaps slightly emaciated. The heart was normal The lungs showed a few scattered râles The abdomen revealed nothing abnormal, the right kidney was easily felt, smooth, not tender, not much enlarged, the left kidney was not felt By the vagina, a small cervical "polyp" was palpated The urine the first few days contained a trace of albumin, little pus, some times a few red blood cells, an occasional granular cast, no tubercle bacilli

Cystoscopy and Catherization—I was asked to try to determine the source of the hematuria At the time of my first examination (January 27), the catheterized bladder urine was clear and microscopically free from both pus and red blood cells Cystoscopy was easily performed, and an excellent view of the bladder obtained. It presented no tumor or calculus, and the mucosa was entirely normal The left ureteral orifice was of normal appearance and in the usual position, and functioned normally In a corresponding position on the right side of the trigon was an orifice with a similar normal elongated contour About 5 mm dorsosuperior and apparently a little mesial from this orifice was a smaller and round depression which was seen to function as a ureteral mouth. Careful observation revealed entire independence of action of these two right ureteral openings They were both easily catheterized and the catheters (No 6 F) were introduced about 25 cm A typical intermittent flow was obtained from each and 5 c.c. of urine simultaneously collected from each in the same interval of time The specimen from the cephalic orifice was almost clear, contained 0 4 per cent urea, no pus and few red blood cells That from the caudal orifice was bloody from the start (a suggestive point, I think), con

---

* Read in the Symposium on Renal Surgery and Pathology in the Section on Genito-Urinary Diseases of the American Medical Association at the Sixty Third Annual Session held at Atlantic City June 1912

tained only 0 2 per cent urea, no pus and much blood The cystoscope was removed from the bladder, catheters being left *in situ*, fitted with another pair of catheters and reintroduced The catheters on the right side were noted to be in position, and the left ureter then catheterized. Its outflow was nearly clear, was microscopically negative but for a few blood cells, and contained 0 6 per cent urea

Urine Test—A phenolsulphonephthalein test was done, 6 mg being injected intravenously Color first appeared in the urine in four and one half minutes During the subsequent half hour the catheter in the caudal ureteral mouth discharged urine very slowly In the first fifteen minutes the left ureteral catheter gave 12 c c. of urine and 16 4 per cent of the drug, the right "cephalic ureter" (an inexact phrase used for brevity) 8 c c and 7 2 per cent, the right "caudal ureter" 2 c.c and 0 3 per cent In the second fifteen minutes the left catheter gave 8 c.c and 11 7 per cent, the right cephalic 5 c c and 3 5 per cent, the right caudal 1.5 c c. and 0 4 per cent Attention is called to these facts Making abundant allowance for a possible extra catheter flow from the caudally placed ureteral mouth, it is to be noted that the right ureter with the cephalic orifice produced less than half as much phenolsulphonephthalein as the left ureter, and that the right "caudal ureter" produced less than half the amount recovered from the "cephalic ureter" It is to be remembered also that the urine from the two right ureters contained about the same relative percentages and amounts of urea, that is, twice as much from the cephalic as from the caudal ureter In other words, the lower (the caudal) ureter mouth was associated with renal tissue of about half the functional ability (at least for excretion of urea and phenolsulphonephthalein at the time of the test) of the renal tissue drained by the other right ureter

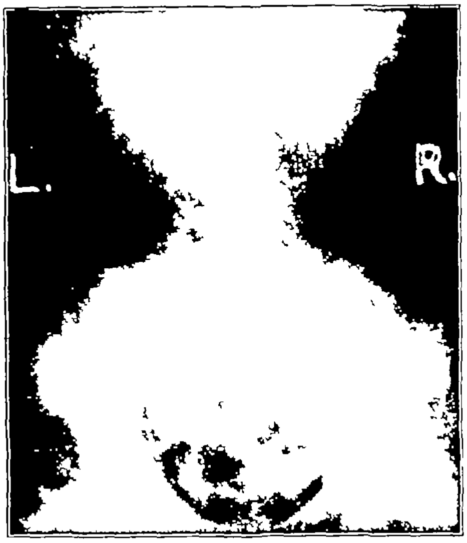

Fig 1—Radiograph with 20 per cent argyrol Left pelvis normal lower right pelvis with tongue like shadows at lower part upper right pelvis very faint

Argyrol Radiographs—With the three ureteral catheters *in situ*, argyrol 20 per cent. was injected into each and a radiograph taken It showed a normal left renal pelvis and ureter, and a smaller right renal pelvis with two thin shadows radiating inferiorly and laterally Mesial to its ureter, another and fainter line was evident leading up to a poorly outlined elongated shadow above the right pelvis just described (Fig 1)

Skiagraphic catheters were passed into the two right ureters, February 2 The catheters were carefully marked, and the one entering the caudally placed ureteral orifice was injected with argyrol (through a misunderstanding it was again only 20 per cent) and a radiograph taken The other catheter was then injected till slight discomfort was produced, and a second plate exposed (Fig 2) In this way t caudally placed ureter mouth was definitely associated with the lower (the caudal) portion of the right kidney This lower portion of the kidney, then, represents a smaller amount of renal excretory function, according to the tests, than the upper portion of the right kidney, yet it is represented on all our *x* ray plates by a larger renal pelvis (but by an abnormal one) draining a larger superior inferior area In view of this radiographic evidence, the function tests, the immediate appearance of blood when the ureteral catheter was passed up to the lower renal pelvis, and the negative bladder examination, the assumption seemed well grounded that if the blood came from the urinary tract, it had its origin in the lower pole of the right kidney and most likely in a neoplasm of this region

Because of the presence of cervical polyps, some doubt was felt as to the source of the blood These polyps were removed Marked hematuria, however, recurred and bladder catheterization fixed the responsibility on the urinary tract

Operation and Result—February 24, Dr Blake operated through a right lumbar incision The fatty capsule of the kidney was adherent on the lower posterior surface A tumor in the kidney substance was evident, and nephrectomy promptly done Blood vessels entering the lower pole of the kidney interfered with the dissection toward the pedicle They were divided between clamps, which also included the lower ureter, as was clear later The operation proceeded as usual Most of the perirenal fat was excised Convalescence was normal and progressive, the temperature never above 100 F, and a good output of urine was noted daily The patient left the hospital March 17

Pathologic Report—The kidney (Figs 3 and 4) is 12 cm long and 4 cm in thickness Presenting from the lower half of the posterior surface, is a lobulated round sharply outlined tumor 4 5 cm in diameter, with a very definite connective tissue capsule On cut section of the fresh specimen, the tumor is seen to form definite lobules arranged in the most part about a common center suggesting a hilum, the color is light yellow The renal parenchyma of the upper part of the organ is normal in appearance and thickness The upper pelvis presents two major subdivisions, each in turn draining three calices, two placed posteriorly one anteriorly These calices are all intact are not associated with the tumor, and [illegible] nect with the other pelvis The lower pelvis is [illegible] the tumor and can be identi [illegible] primary dila [illegible]

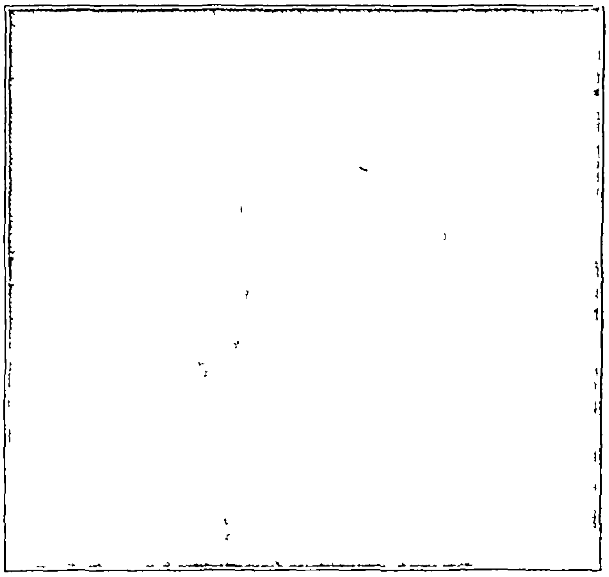

Fig 2.—Radiograph with 20 per cent argyrol (too weak) showing two right renal pelves overlapping (non-communicating) and lead impregnated catheters in double ureter

blood vessels entering the kidney are distributed along the anterior aspect of the hilum, and a few posterior to the lower pelvis None of the veins contain tumor material

Microscopic Examination—Microscopically the tumor shows a mass of large epithelial cells with relatively small nuclei and clear cytoplasm, arranged in alveoli supported by a very delicate framework of connective tissue branching from dense trabeculæ At points the alveoli form an adenomatous structure The tumor seems well encapsulated and no invasion of renal parenchyma or pelvis was found It evidently belongs to the group of tumors classed as hypernephromas, and was so diagnosed by Dr W C Clark of the pathologic department of the hospital.

LESIONS ASSOCIATED WITH DOUBLE URETERS

Double ureters may be incomplete or complete, that is, they may join and enter the bladder through a common opening or may remain apart and enter the bladder through independent openings Normally in embryonic life the renal bud, soon after its appearance as an outgrowth from the wolffian duct, splits terminally into cephalic and caudal portions, which ultimately become the two main divisions of the pelvis That portion of the wolffian duct between the renal bud and the cloaca becomes absorbed in the cloaca, thus affording separate openings for ureter and wolffian duct (the future vas deferens) Double ureters are thought to originate from double budding from the wolffian duct or by extension downward of the split occurring normally at the end of the renal bud It seems likely that an extra renal offshoot gives rise to another fully developed pelvis and its development in adult life should be regarded as a supernumerary kidney, whether separated from or joined to its neighbor of the same side The cleavage process, however, is regarded as the more probable explanation of reduplication of ureters (Meyers,[1] Pohlmann[2] Huntington[3]) When the cleavage is complete, one finds completely double ureters — ureters with independent openings in the lower urinary tract Subsequent development and unequal growth of the region of the lower ends of the ureters cause an apparent rotation which brings the orifice of the ureter from the upper pelvis mesial to and usually mesial and caudal to the orifice of the ureter from the lower pelvis, and the opening of the wolffian duct caudal to the ureter Moreover, the lower pelvis, which as a rule is the larger, usually empties into the bladder at the *normal* site for a ureteral opening on the trigon

I have outlined briefly these features of development to call attention to the fact that in the case here reported, the ureter from the lower pelvis did empty into the part of the bladder normally receiving a ureter, but contrary to rule, its fellow opened not distal but proximal to it I have found but one other such instance, a report by Kerr[4] of an exactly similar relation of orifices of double ureters in a post-mortem observation

It will be noted that, according to the *x*-ray plates, the ureters do not cross in their course from kidney to bladder If they cross in a given case they must recross, as the ureter from the upper pelvis starts mesial and ends mesial to its fellow

Because of the idea that many neoplasms have as a basis some congenital abnormality, and regardless of one's views concerning the histogenesis of hypernephromas, one is at first impressed with the association of this renal tumor with a congenital anomaly of the collecting apparatus Yet embryologically I can see no relationship beyond the possible evidence of a general tendency of the particular organism to congenital abnormalities The reduplication usually concerns the collecting apparatus only, not the kidney parenchyma which is derived from another and very different source In fact, in these cases of double ureter the kidney has as a rule the contour of a normal organ, moreover, I have found no other instance of hypernephroma of the kidney associated with double ureter and pelvis The nearest approach was a case of Kapsammer[5]—hyperne

Contrary to the view of older writers, ureter duplication, in part or in whole, has a decided clinical interest and importance but only in recent years has a diagnosis been made before operation or necropsy Kapsammer observed in 1905 perhaps the first case of bilateral complete doubling of the ureters diagnosed during life The four orifices were catheterized and the two pelves of each kidney proved non-communicating by the injection of indigocarmin into one ureter and its failure to return through the other The two right ureters gave normal urine, both left ureters discharged a little pus This was cleared up by lavage

Seelig[6] reported last year another case (observed in 1910) of this bilateral complete duplication with radiographic plates showing collargol in the four pelves and bismuth-impregnated catheters in the four ureters Clinically his observations were most interesting — the right upper pelvis gave albumin and epithelial and blood-casts, the right lower pelvis, normal urine the left upper pelvis, a definite amount of pus but no casts, the left lower pelvis, only a few leukocytes

B Lewis[7] and Newenow[8] reported cases of double ureters on the left side, with clear urine from one and pus (and gonococci in Lewis' case) from the other (determined by catheterization) The infection in both instances was cleared up by pelvic lavage

Similarly Franke (quoted by Pasteau[9]) in a patient with two ureters from the right kidney, found one ureter excreting clear, and the other purulent urine By operation, an artery crossing and partially obstructing one ureter was divided, and the patient's symptoms were relieved Kapsammer's case of extensive tuberculosis of a left kidney having complete double ureter is of no special significance in this connection

Of the reported cases of renal diseases associated with incomplete double ureter, those of Stark[10] and Wulff[11] are notable as having been correctly diagnosed before operation The former on different days obtained clear and purulent urine from the left kidney, the output from the right kidney being always normal Stark inferred that there was a bifurcation of the left ureter, and that his catheter had entered different pelves on the two examinations Operation confirmed the diagnosis The upper part of the kidney was normal, as was its ureter, in the lower part there was a pyonephrosis, and its ureter was much thickened Stark feared infection of the remaining portion should he attempt a resection of the kidney, and consequently did a complete nephrectomy Subsequent recurring infection of the bladder from the ureteral stump would seem to confirm his judgment Wulff, in his case, obtained purulent urine from the ureteral catheter in the left ureter, but clear urine when this catheter was pushed higher A forked ureter with two pelves, one infected, the other normal, was found at operation

Rafin,[12] Kapsammer,[5] Israel[13] and Dumitreanu[14] report instances of infected kidneys each with two pelves and two ureters (i e, a double ureter in at least its upper portion), discovered only at operation In all of these four specimens, the infection (tuberculosis in Kapsammer's patient) was confined to the part of the kidney associated with *one* pelvis, while the other portion of the organ was normal Kusnetsky's case[15] was similar, additional interest was afforded by the presence of a large stone in the ureter associated with the pathologic pole of the kidney at the junction with its fellow ureter

Bruel's report[16] concerned a like condition superficially One end of the organ was virtually a pus sac, but the other with its ureter appeared normal On section this supposedly normal pole showed miliary abscesses and intense interstitial infiltration An attempt at resection here would have been worse than futile Nevertheless a successful resection of a pyonephrotic sac with a part of its ureter, leaving the upper portion of the kidney and its ureter, was reported by D'Lennander[17] He first did a lumbar nephrotomy and later appendectomy and the partial nephrectomy through an abdominal transperitoneal wound Probably one would feel justified in doing a heminephrectomy in few cases of infection of one-half a kidney with two pelves and ureters, for fear of subsequent involvement of the remaining portion Just which cases are suitable is a matter for individual judgment The difficulty of such an operation would depend largely on the arrangement of the blood-vessels If the kidney substance should possess independent blood supply at either end, and the intervening portion be of smaller diameter than the ends, as in Albarran's case,[18] the operation is comparatively simple His patient had a lumbar fistula following nephrostomy performed by another surgeon Ureteral catheterization disclosed a normal left kidney and a good quality of urine coming from the right ureter Fluid injected into the latter did not come out of the nephrostomy wound The anomalous condition found at operation was not suspected before Albarran speaks of the findings as "two kidneys" placed one above the other, joined together, but each having its own blood-supply as well as pelvis and ureter The upper end was pyonephrotic and was excised Apparently no mention is made of the termination of the ureter from the excised kidney If it ends in the neighboring ureter, one ureter probably represents embryologically an abnormal sprout from the other ureter Such an explanation was offered by Huntington for a similar museum specimen

The reports of Young[19] and Key[20] demonstrate that double ureters may be the cause of serious mistakes The former recited the details of an interesting well-studied case of renal calculus Pus was obtained from the right ureter, clear urine from the left A radiograph showed a large calculus filling the right renal pelvis, but none in the left kidney Right nephrolithotomy was performed The autopsy disclosed two pelves in the left kidney, and two ureters joining before reaching the bladder The upper pelvis contained calculi and pus but its ureter was plugged up, and the ureteral catheter passed on the left side went up to the normal pelvis The *x*-ray plate had been placed too low to show the left renal calculus Briefly, Key's patient presented a double renal pelvis on the right side There had been pus in the urine, but none was present at the time of the examination A radiograph gave a shadow mistaken for stone This proved to be a tuberculous abscess in the upper part of the kidney Here again the ureter draining this region was plugged, and only clear urine from the other pelvis reached the bladder from the right kidney

Lastly, von Fedorow[21] reports an interesting case Two normal ureteral openings were seen which on catheterization gave normal urine from the right side and a little pus from the left Lateral to the left ureteral orifice was a thin-walled cyst At operation, this was incised, found to lead upward to a ureter running close to the other left-sided one but without connection with it A plastic operation was done on the cyst, relieving the symptoms — pain in the left kidney and frequent and painful urination Six months later, the original left ureteral orifice gave urine free from pus, while its fellow, which at first probably had only a very small bladder opening but now had a large one, produced urine containing pus

I have arbitrarily omitted the general subject of stricture of the ureter (a matter thoroughly discussed in comparatively recent papers, notably that by Bottomley[22]), and have considered only cases of double ureter presenting some associated renal lesion other than a possible hydronephrosis caused by congenital stricture of the ureter In Bottomley's collection of fifty-six cases, eleven patients had supernumerary ureters

Concerning the frequency of double ureters, Kerr[4] reports four instances of unilateral complete double ureters in 165 dissecting-room subjects, Pohlmann,[2] two complete double ureters in over sixty embryos, G M Smith,[23] three incomplete double ureters (bilateral in two cases) in 100 autopsies, in general autopsy work, unilateral double ureters are recorded in from 1 to 4 per cent, and more frequently on the left than on the right side I find no justification for Stark's statement that incomplete doubling is usually unilateral, and complete doubling usually bilateral Complete doubling with two bladder orifices is rare compared to incomplete doubling (Huntington), yet, as several writers have pointed out, in the former cases the two ureters are bound tightly together in their lower third and a complete case might easily be mistaken for an incomplete case, unless the ureters are carefully dissected Bilateral complete duplication of the ureters is decidedly less common Gould[24] in 1903 reported two such autopsy cases and said that he could find but eight others in the literature, I have come across eight instances of this condition reported since 1903 (Kapsammer,[5] Wwendensky,[25] Rendu,[26] Huntington,[3] Furness,[27] Decherd,[28] Comolli[29] and Seelig[6])

Lichtenstern[30] reported a case diagnosed clinically as crossed ureters I know of no such post-mortem observation Kapsammer[5] has seen three cases which he interpreted as duplication of only the lower end of a ureter, simulating an *inverted* Y He records no radiographic demonstrations, or irrigation test such as he employed to prove absence of communications of the two pelves of a kidney with complete double ureters Embryologically such a condition is "contrary to nature" and most writers seem to think that it never occurs, but that for every ureteral opening in the bladder there is at least one renal pelvis that, when more than one, these pelves communicate rarely and only as the result of pathologic processes As many as six ureteral orifices in one bladder have been reported (Schewkunenko[31]), and five cephalic divisions of one ureter (Glazebrook[32]) When one searches for other possible stumbling-blocks, the various renal malformations and ectopias come to mind, and the occasional presence of a third kidney or the rare occurrence of but one kidney The many possible terminations of ureters, other than bladder, must also be remembered

In conclusion, if one will except the rare true cases of solitary kidney, when a blind ureter may be found on the other side extending up a short distance from the bladder, the inference is certain that for every ureteral orifice in the bladder there is a renal pelvis — perhaps more than one — and that these pelves do not communicate Also there may be present ureters terminating at their distal ends blindly or in some part of the genital or urinary tracts other than the bladder When a ureter crosses the median line to reach its associated kidney, that kidney is usually caudal to the one normally belonging on that side Of two ureters running from one kidney to the bladder, that with the more mesial and more caudal opening almost always corresponds to the upper pelvis of the kidney The history and general examination will offer valuable leads, but our surest means of diagnosing renal conditions accurately are careful comparative examinations of urines obtained by ureteral catheter, associated kidney function tests, and intelligent use of the *x*-ray In baffling cases urine from different levels of the ureter should be collected and it is best to inject the silver solution through a large catheter first in the renal pelvis, then at successively lower points in the ureter, before radiographs are made

40 East Forty First Street

ABSTRACT OF DISCUSSION

Dr **Hugh H Young**, Baltimore The surgery of the double ureter is very interesting and complex and frequently leads us into a wrong diagnosis I reported just recently in New York before another society an interesting double ureter case, in which when I first looked into the bladder I saw a diverticulum, but when the patient strained an immense prolapse came out, over which I found the ureter I operated and found, instead of a diverticulum, another ureter In another interesting case, catheterization showed pus issuing from the right ureter and clear urine from the left. I took an *x* ray plate which seemed entirely satisfactory and which showed a mass of stones in one kidney quite high up, on the other side I could see the apparent outlines of the kidney The patient was operated on and promptly died of uremia At autopsy we found that above the apparently healthy kidney was another kidney which had a big stone in it The *x* ray plate had just missed it The patient had two ureters on that side in the upper part, and a single one below

Dr **Edwin Beer**, New York I have seen during the last forty eight hours one of the most baffling cases that I have had the opportunity of examining The patient complained of chronic pyuria In 1902, this patient had been operated on for subphrenic abscess The abscess refused to heal, and a secondary operation was done by a New York surgeon, who removed the kidney which had been the source of the original abscess The sinus again refused to heal, and a partial ureterectomy was done The pyuria continued Subsequently to the operation a fecal fistula developed The patient was operated on for the fourth time as the fistula refused to close. The pyuria continued. There was a mild form of sepsis. A ureterectomy was done, but still the pyuria continued. The patient came to me about ten days ago. I washed the bladder out regularly, but the pyuria did not diminish. June 3 I cystoscoped him, and I found on the right side a ureter 25 cm long, full of foul pus. On the other side there was no sign of a ureter, but an enormous pouch. At first I thought this was a case in which the surgeon had not taken out the ureter, although he had operated for the ureter on two occasions, but on further consideration I am forced to conclude that the patient must have had a double ureter. Another case bearing on the same question was a patient with a double ureter which we proved on the cystoscopic table. One ureter was closed; mesial to the ureter there was a tiny point from which indigo carmin escaped. The second ureter was 37 cm long, and at operation we found that it led to the upper pole, which was normal, the lower pole being the seat of a hydronephrosis.

DR. J. B. ROXBY, Swarthmore, Pa. An experience in the dissecting room for a period of years confirms the fact that a large percentage of double ureter cases are in existence without having been known. An interesting case was seen recently in which there was a double ureter on the left side, the larger ureter was draining a small segment of kidney, the superior portion, while the small ureter was draining the majority of the kidney substance inferiorly. The caliber of the pelvis of the upper kidney substance was very much greater than the caliber of the lower kidney substance.

DR. A. R. STEVENS, New York. Dr. Young's case of bilateral renal calculus was referred to in the paper, but I omitted it in the reading because of lack of time. According to various statistics, double ureter, either complete or incomplete, occurs in from 1 to 4 per cent. The latter figure is probably nearer the facts, and hence warrants thoughtful consideration of the subject and watchfulness for these anomalies. While one should be mindful of all the possibilities in a given instance, from the data afforded by radiographs taken after injection of argyrol or collargol in the ureters and pelves one may learn precisely the course and cephalic ending of each ureter. Indeed, in some cases thought to be anatomically normal the shape of the pelvis may warn the observer of an overlooked ureter.

AN OVERLOOKED FUNCTION OF BARTHOLIN'S AND COWPER'S GLANDS

D. T. SMITH, M.D.

LOUISVILLE, KY.

In the male and female of all the higher animals, in connection with the sexual system, are found two sets of homologous glandular organs, much of the importance of whose office seems hitherto to have been overlooked. These are Bartholin's glands in the female and Cowper's glands in the male.

The fact that Bartholin's glands supply a mucus for the lubrication of the entrance to the vagina during sexual excitement, and that Cowper's glands secrete a mucous fluid which acts in part as a vehicle for the seminal discharge has long been noted. But each has a supplementary office in connection with the discharge of the urine, to which, so far as I know, reference has never been made, though one of distinct importance.

Every one who has suffered with irritability of the neck of the bladder or the bulb of the urethra is aware that immediately after voiding the urine an intermittent contraction is experienced in these parts for several seconds, which then gradually fades away. Such contractions, no doubt constantly present in the healthy subject, are probably experienced by the whole class of mammals; they indicate a double function for the glands.

One of these functions has already been mentioned as being related to the requirements of procreation. The other relates to the protection of the mucous membrane of the vestibule and adjacent parts in the female and of the urethra in the male against the irritating action of the urine.

When the urine is passed the mucous membrane is in large measure swept bare of its free mucus, and this privation Nature set out early to remedy. In accomplishing her purpose she found ready to hand the before mentioned glands, already developed for the accomplishment of an important office in the way of facilitating reproduction. These glands, like all other animal tubes or hollow organs, have their walls constructed in part of an external layer of longitudinal muscular fibers and an internal circular layer, a plan of structure which seems to have come up from the worms.

As soon as the act of urination has ceased a contraction of the walls of these glands takes place, extruding mucus into the passages to take the place of that which has been washed away by the passing urine, thus protecting the denuded mucous membrane. The contraction of the gland walls is reenforced by that of the walls of the urethra in the male, and in the female, by the contraction of the muscles about the outlet of the vagina. It is probable, too, that in all cases a reflex stimulus is conveyed to the glands which causes an increase in the quantity of their secretion.

In the mare, the contraction on the spongy, yielding tissues within the sphincters is so considerable that the vulva becomes quite everted under its operation. In the females of many other animals a distinct intermittent protrusion of the vulva may be observed under similar circumstances.

In the practice of medicine this condition is often a matter of distinct importance. In a large percentage of males the secretion is poured out with sufficient copiousness to cause it to be discharged from the urethra as a stringy mass, and the cases are without number in which men have consulted their physicians about an imaginary spermatorrhea, or have shamefacedly submitted to be robbed by conscienceless quacks, when nothing worse was going on than a beneficent effort of Nature to protect the mucous membrane against irritation by the urine. To the advertising quack this delusion has proved to be a veritable gold mine, and if statistics could be gathered of the amount of money annually paid out to these gentry by uselessly alarmed multitudes, the sum would be found absolutely astounding.

Field of Prevention.—The more we study preventive medicine and sanitation the wider grows the field, until we find that our horizon is almost boundless being coincident with man's energies and ambitions and wherever he goes and whatever he does we must henceforth stand by his side and guide him safely. No longer can our efforts or duties be limited by the actual presence of disease entailing the necessity for cure or for prevention of spread. We begin with the cradle, and in ordering the proper diet, clothing, temperature, air and exercise for the young child and watching his eyes, teeth, ears, nose and pharynx, we give him a better start in life than his father had. We follow him through school with the same care and see that he does not overtax his growing muscular system at football, baseball, rowing, track or gymnasium. When he goes into business it is, or ought to be, our duty to see that the office building, store or factory is built ventilated and heated aright, to see that the workers in all trades have plenty of fresh air to breathe, do not work in cramped positions, are not allowed consumptive fellow workers, have good water to drink, have decent privies or water-closets, have time to eat their midday meals and not bolt them as some ravenous beast.—White in *Wis. Med. Jour.*

EFFECT ON LATER DEVELOPMENT OF SEVERE AND PROLONGED ILLNESS IN INFANCY *

THOMAS D PARKE, M D
AND
JOHN H EDMONDSON, M.D
BIRMINGHAM, ALA

This study was undertaken, in the absence of published data, for personal considerations of curiosity and interest, since each one of the patients has been attended through serious and prolonged illness involving inanition of decided degree No case that did not represent extreme conditions of illness and prolonged interference with nutrition has been selected Tables of average measurements from text-books of Holt and Koplik have been utilized for comparisons

Case 1—B S, a white boy aged 7 years 1 month, breast raised Ileocolitis at 13 months of age, temperature 104 on first day, bloody stools at frequent intervals, hopeless prognosis given family, by consultant, on fourth day, corneal surface lesion on fourth day, attributed to intensity of infection Illness extending over three weeks and convalescence attended by a marked degree of inanition lasting for another month

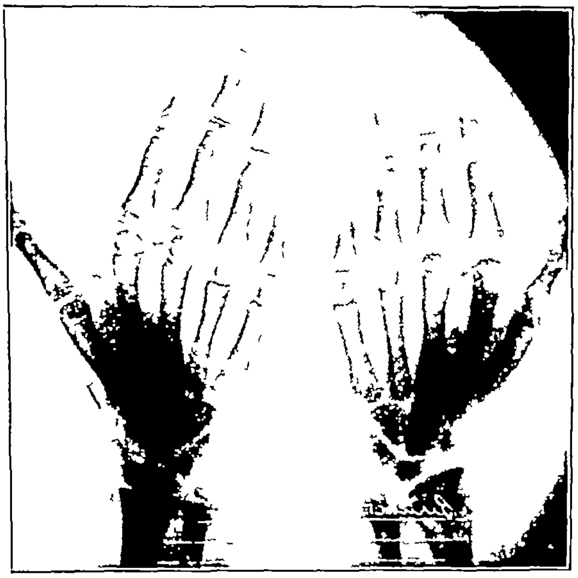

Fig 1—Case 1 The epiphysis of the ulna is undeveloped The semilunar is likewise undeveloped The wrist is below that which is normal at the age of 6¾ years Actual age of patient 7 years 1 month

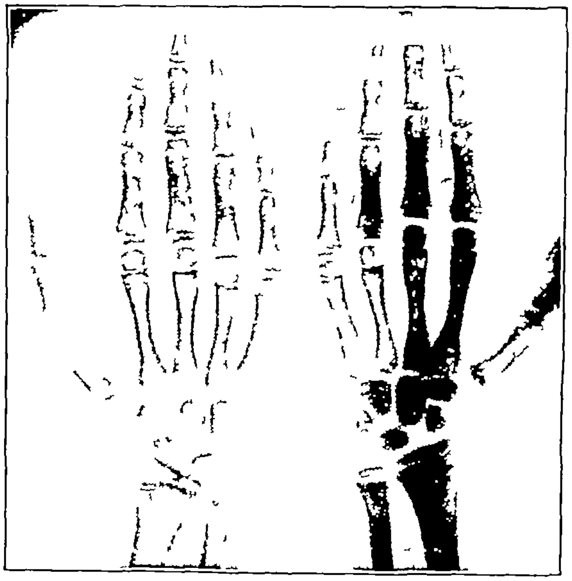

Fig 3—Case 4 All bones are present as expected for this age but not more developed than for 6¾ years Actual age of patient 9 years 3 months

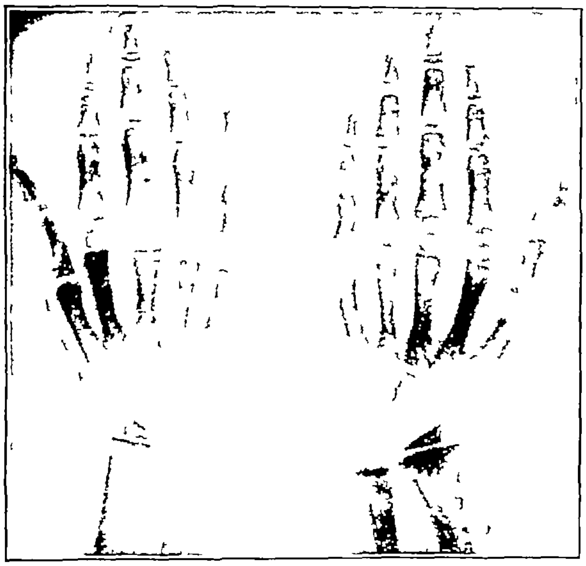

Fig 2—Case 3 The development of bones in the wrist is equivalent to that of the age of 3½ years. Actual age of patient, 6 years 10 months There are no epiphyses of the ulna and no scaphoid.

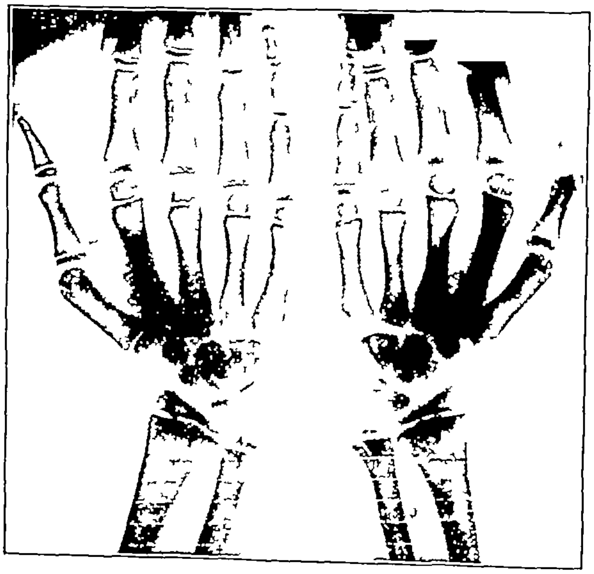

Fig 4—Case 5 The epiphysis of the ulna is much underdeveloped the development corresponding to that of the age of 6 years. Actual age of patient, 8 years 11 months See Plate 35 Rotch

Measurements, May, 1912

		Average of His Age
Height (inches)	50 1/2	46 1/2
Weight (pounds)	59	49 1/2
Chest (inches)	25	23 7/10
Waist (inches)	25 1/2	

Case 2—G C a white boy aged 6 years 1 month, breast raised At two years of age suffered from severe ileocolitis high temperature from beginning, severe nervous symptoms,

---

* Read in the Section on Diseases of Children of the American Medical Association at the Sixty Third Annual Session, held at Atlantic City June 1912

manifested by screaming, insomnia of marked degree, self injury necessitating splinting of arms and finally restraint of the wrists, emaciation marked Convalescence prolonged Patient, a bright, vigorous child not yet of school age

Measurements, May, 1912

		Average of His Age
Height (inches)	47 3/4	44
Weight (pounds)	46 3/4	45
Chest (inches)	22	23 2
Waist (inches)	22	

Case 3 —S K, a white boy aged 6 years 10 months, breast raised Ileocolitis at 20 months of age, high temperature for a week with frequent bloody actions Development of meningitis and for ten days a fatal issue apparently inevitable Patient blind for a month after unconsciousness passed off Prolonged convalescence, emaciation extreme

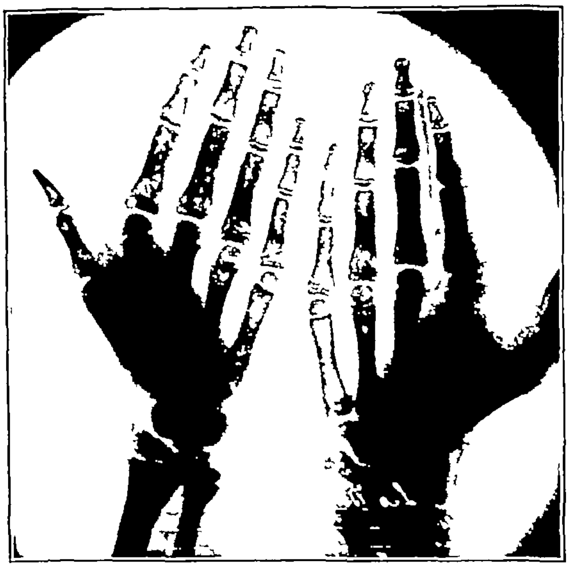

Fig 5 —Case 6 The development of the pisiform is three years ahead of the patient's age corresponding to that of 8¼ years (Rotch) Actual age of patient 9 years.

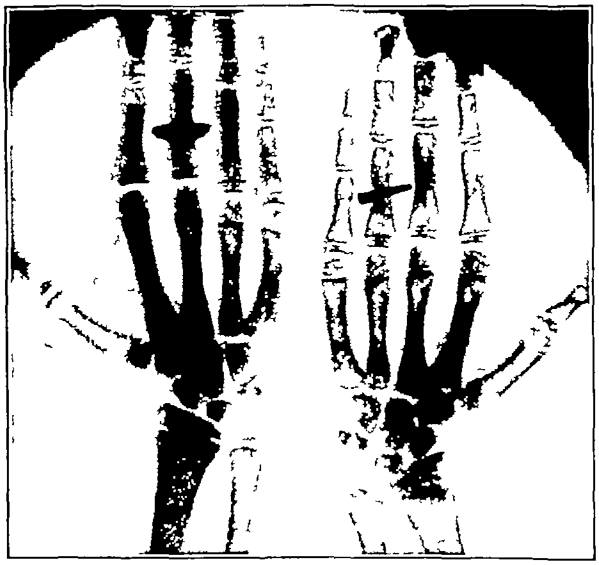

Fig 6 —Case 7 The epiphysis of the ulna is much underdeveloped The wrist corresponds to the normal wrist at 6¾ years. Actual age of patient 8 years 10 months

Measurements, May, 1912

		Average of His Age
Height (inches)	47 1/2	46
Weight (pounds)	47 1/2	49
Chest (inches)	23 1/4	23 7/10
Waist (inches)	22	

Case 4 —N W, a white boy aged 9 years 3 months, breast raised to 7 months Shortly after weaning was forced through illness of mother, ileocolitis developed, temperature not so high as in most of the other cases, but disease ran a prolonged course and emaciation was extreme, at 6 years patient developed endocarditis as the result of tonsillitis, and valvular lesion existed since He is bright and active and did well at school, he chafes under restrictions on fatiguing exercise, counseled by valvular leak Measurements, May, 1912

		Average of His Age
Height (inches)	53 1/2	50
Weight (pounds)	65	60
Chest (inches)	25	25 1/10
Waist (inches)	24	

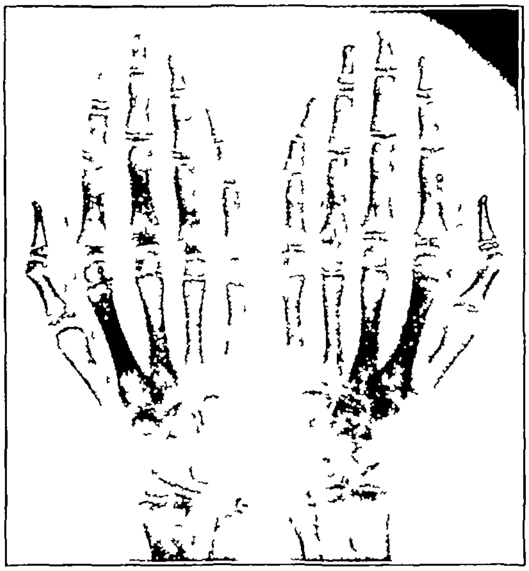

Fig 7 —Case 8 The development corresponds to that of slightly under 9 years based on lack of compactness and size Actual age of patient 9 years 11 months.

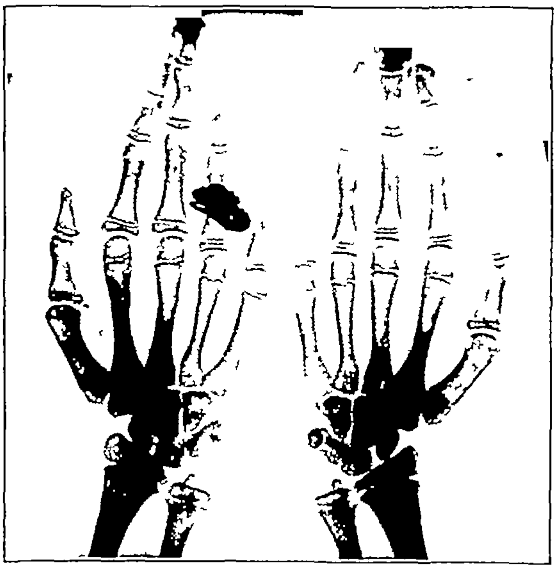

Fig 8.—Case 13 The styloid of the ulna is larger than normal The wrist is about normal Actual age of patient 10 years 5½ months

Case 5 —P P, a white boy aged 8 years 11 months, breast raised, first seen at age of 2¾ years, suffering from chronic dysenteric condition dating back nine months At age of 3 years bronchopneumonia, patient critically ill for a month, extremely emaciat [illegible] dition [illegible] been relieved For [illegible] d on account tonsils and adenoids have been removed in last six months, recommended on account of ear complication The child is doing well at school

Measurements, May, 1912

		Average of His Age
Height (inches)	52 3/4	50
Weight (pounds)	63	60
Chest (inches)	24 1/2	25 1/10
Waist (inches)	25	

Case 6—L S, a white boy aged 9 years, breast raised At 2 years of age severe attack of ileocolitis, fever three weeks, prolonged convalescence Emaciation extreme Metabolism affected for months Patient doing well at school

Measurements, May, 1912

		Average of His Age
Height (inches)	54 1/4	50
Weight (pounds)	67 1/2	60
Chest (inches)	27	25 1/10
Waist (inches)	27	

Case 7—C M, a white girl aged 8 year and 10 months, at 15 months of age severe attack of acidosis, with marked enlargement of the liver, labored breathing and prostration, inability to take any food for seven days, digestive capacity so affected by the acidosis that nutrition was seriously affected *for more than a month* Patient doing well at school, an unusually active girl

Measurements, May, 1912

		Average at 9 Years
Height (inches)	51 1/4	49 6/10
Weight (pounds)	65	57 1/2
Chest (inches)	24 1/2	24 9/10
Waist (inches)	24	

Case 8—H C, a white boy aged 9 years and 11 months, breast raised, brother of the patient in Case 2 At 11 months suffered from ileocolitis, complicated by acidosis, enlarged liver and labored breathing Patient extremely ill, colitis with malassimilation for a month following, with extreme emaciation Slow convalescence in a cooler climate. Patient active, bright, and high in his studies

Measurements, May, 1912

		Average at 9½ Years
Height (inches)	55 1/4	50
Weight (pounds)	69 1/4	60
Chest (inches)	26	25 1/5

Case 9—M A., a white girl aged 13¼ years, breast raised, at 16 months suffered an attack of ileocolitis ushered in by convulsions lasting for two days Continued high fever for two weeks, malassimilation due to intestinal condition lasting for more than six weeks Extreme emaciation, from age of 8 to 12, patient subject at times to attacks of acid intoxication of mild degree, tonsils removed at 12½ years

Measurements, May, 1912

		Average at 13½ Years
Height (inches)	61	58 1/2
Weight (pounds)	92 1/2	91
Chest (inches)	29	27 7/10

Case 13—L N, a white girl aged 10 years, 5½ months, breast raised, at 18 months of age suffered from ileocolitis complicated by acidosis, with enlarged liver, labored breathing and marked prostration After acidosis symptoms passed off colitis accompanied by high fever continued for two weeks Marked interference with digestion and assimilation continuing for more than a month after the child was taken to the shores of Lake Michigan, emaciation extreme

Measurements, May, 1912

		Average at 10½ Years
Height (inches)	57 1/4	51 7/10
Weight (pounds)	86 1/2	64
Chest (inches)	26	24 7/10

Cases 10, 11 and 12 are normal so far as concerns serious illnesses and were selected because they were above the average in vigor and appearance

The interpretation of the skiagrams, by Dr Edmondson, is given in the legends

Idiosyncrasy in Gout.—In no disease does idiosyncrasy, that great stumbling block in therapeutics, make itself more evident than in gout —Samuel West in *Clin Jour*

THE CALORIC REQUIREMENTS OF BOTTLE-FED INFANTS *

ROGER H. DENNETT, M D
Instructor in Pediatrics, Assistant Attending Physician in the Babies Wards New York Post-Graduate Medical School and Hospital
NEW YORK

There still seems to be a great difference of opinion among pediatrists as to the necessity of carefully computing the number of calories per kilogram or pound weight in every bottle-fed infant The percentage method of feeding has so thoroughly embedded itself in the minds of American infant-feeders that the caloric requirements are usually entirely ignored or simply used as a check As a matter of fact, this expression, "used as a check," usually means that the feeder either prescribes the food symptomatically, his experience in feeding having been great enough to allow him to guess at the quantity and strength, or he has certain rules of his own to go by When the baby is not doing well, he reckons up the calories to see whether that individual child is getting a great deal more food than he needs or perhaps a great deal less Another expression which is frequently used at the present time and which I have myself been guilty of using in the past is "thinking in percentages" However much a physician knows about percentage feeding, and however successful he may have been in using it he cannot realize how much more accurate and successful his feedings would be if he would substitute for this or add to it "thinking in calories" It would hardly seem necessary to remind infant-feeders of the fact that the caloric requirements of adults have been worked out carefully and are used in a practical manner in the treatment of nephritis, diabetes, typhoid and many other conditions How much easier it is to reckon calories in the bottle-fed baby who is fed definite quantities of milk, cream, sugar or gruels, than it is the more complicated diet of adult life!

Another criticism that I would like to make of those who do not reckon calories (and they are becoming fewer every day) is that their remarks are founded on their inexperience with this particular method. They have not followed week after week the calories of the babies which they are feeding, and therefore they do not realize the help that it will give them They also seem to think that when they use the caloric method they do so to the exclusion of the digestibility and suitability of the food for any particular infant This, of course, is entirely untrue, because before the infant is given the number of calories necessary for his nutrition and growth all digestive disturbances must be overcome Even though his caloric requirements are much greater than are supplied in the food that we are giving him while overcoming the digestive disturbances, we always have in mind the number of calories which we shall eventually have to give before he will gain in weight.

It is also held by those who are not in favor of caloric methods that caloric requirements of the individual baby vary so greatly that it is impossible to determine definitely what any one child does need It was with this idea in mind that I started the work of this present paper My previous experience had taught me that some babies do require a great many more calories to gain on than others, and I sought some method of determining their individual caloric requirements I therefore measured the food consumed, retained and digested each day over a prolonged period in a fairly large number of healthy infants of different ages, weights and habits of activity, and in infants in the various stages of nutritional and digestive disorders In this way I attempted to find out the minimum amount of food on which a baby would thrive and gain in weight and the maximum amount which causes digestive disturbances or cessation of gain in weight I then classified these babies in a rough way for practical help in well on them and the source of error is less than when we use more complicated feedings Milk of which the fat-content was known was used The sugar, which from its high caloric value might easily be a source of error, was carefully measured in accurate containers which I furnished the parents I have used either cane-sugar or malt-sugar (dextrimaltose) It may be possible that the caloric requirements of infants fed with other foods than simple whole milk mixtures differ from those of my patients First I shall show a tabulated

feeding sick and well babies For my experiments I selected babies living at home, whose mothers I could rely on for intelligence, accuracy and truthfulness Naturally most of these were private patients, as it is notorious that bottle-fed babies do poorly in hospital wards I myself examined the stools continuously in each case, and unless they were normal and there was no vomiting, the number of calories which they received was not considered of importance

I have used simple milk mixtures of whole milk, water and sugar, because such feedings are digested so much more easily than top milks The babies thrive as feeding record of four cases, and then give the results of the rest of my cases as a whole

CASE 1—Normal infant artificially fed from birth It will be seen that on the third day when it was determined that the breast milk could not be used, I gave a mixture containing no sugar but 2 ounces of milk and 8 ounces of water, making 10 ounces of food in twenty four hours This contained only 40 calories in twenty four hours, or 12 calories per kilogram, or 6 calories per pound the child weighing 7 pounds, or 3 2 kg The food was increased gradually there being no gain in weight until after two weeks, when with 1½ ounces of sugar, 8 ounces of milk and 12 ounces of water, the total calories had reached

340 or 103 per kilogram and 48 per pound During these six days from June 5 to June 11, the child had gained 6 ounces, or 1 ounce per day June 11, the weight being 7 pounds and 6 ounces, or 3 4 kg, the food was increased to 1½ ounces of sugar, 10 ounces of milk and 11 ounces of water, making the mixture which was nearly half and half milk and water Formerly this would have been considered an irrational food for a child 3 weeks of age This gave us 380 calories in twenty four hours, or 112 calories per kilogram, with a gain in weight of only 2 ounces in eight days, which was not so good as during the previous week when the child was getting only 103 calories, and therefore needs an explanation I find that babies who have apparently been more or less starved will at first gain on fewer calories than they really need, but if this food deficient in calories is continued, the gain in weight will cease Therefore the next week I increased the calories to 135 per kilogram or 60 per pound, with a gain of 1½ ounces per day or even a greater one kept up continuously until the two weeks preceding October 1 and October 8, when on 110 calories per day there was a gain of only 0 3 and 0 4 ounce a day, respectively From then on the child gained on a greatly diminished number of calories down to 81 per kilogram, or 35 per pound The reason for this is that the child was then over 5 months of age, and a very fat baby, weighing 15 pounds and 2 ounces, and at 7 months, 20 pounds and 12 ounces To summarize this case, my object was to find the minimum number of calories on which the baby would make a fair gain in weight, repeatedly allowing the calories per kilogram or pound to sink down to a point at which the gain ceased This procedure I followed in most of my other cases I found repeatedly that during the earlier months, a child will cease to gain on less than 110 calories per kilogram, or 50 per pound

CASE 2—Normal child fed from 1 month of age, because of the mother's death The weight was 9 pounds and 14 ounces,

It will then be seen that the food was unchanged for one month and therefore as the weight increased the calories per kilogram and per pound diminished until at the end of this time they got down to 107 calories per kilogram, or 48 per pound by July 9 The child was fed from July 9 until the 16th on 107 calories without any gain in weight The food was again increased to 1½ ounces of sugar 17 ounces of milk and 11 ounces of water, giving 121 calories per kilogram, or 54 per pound, with a gain of 4 ounces in five days, or 0 8 ounce a day, and the following week with the increase of 1 ounce of milk making 123 calories per kilogram or 55 per pound with the gain of 1 ounce per day Again the food remained unchanged for about one month (with the exception of two days when the sugar was left out through an error) until by the increase of weight the calories per kilogram had sunk to 108, or 49 per pound, when we got a gain of only 3 ounces a week, or 0 4 ounce a day This was a repetition of the diminished gain in the week previous to July 16 on 107 calories The following week the increase in calories to 118 per kilogram gave a gain of 1 1 ounces per day and this gain

and the child was put on one half ounce of sugar, 8 ounces of milk and 20 ounces of water, which gave 48 calories per kilogram and 22 calories per pound with no gain in weight The following week the milk was increased to 97 calories per kilogram, 44 per pound with no gain in weight The following week, with 110 calories per kilogram, and 47 per pound, there was a gain of 8 ounces, or 1 ounce per day This child then was kept on food representing more than 110 calories for nearly three months, until the week preceding April 21, when it had gained 5¼ pounds, or an average of over 1 ounce a day throughout this period It was then a fat, healthy baby of over 4 mounths of age, weighing 15 pounds and 4 ounces and, at this weight and age, gained on fewer calories Each week the food remained unchanged, the weight, as it increased, decreasing the number of calories per kilogram or pound, until in the week preceding May 12 the child had gained only 0 3 ounce a day on 94 calories per kilogram On increasing the calories up to 100 per kilogram, there was a gain of 10 ounces a week, or 1 4 ounces per day

This child will go on gaining on less calories as it gets older and fatter, until it will do well on about 80 calories per kilo gram, or 35 per pound As far as the feeding itself is concerned, it will be seen that at 3 months of age the child was getting two thirds milk and one third water with 1½ ounces of sugar added to the twenty four hour amount

Case 3—Diarrhea with overfeeding This child, 2 months of age, weighing 9 pounds and 3 ounces, did well, making good gains on 109 to 128 calories per kilogram, or 50 to 58 per pound The week preceding June 3, the calories were raised to 140 per kilogram, or 63 per pound, and the child made a gain of 1 1 ounces per day, and stood this number of calories for one week very well The following week, however, on the same number of calories, a diarrhea occurred We all know that a child will stand any abuse in feeding for a number of weeks sometimes, without succumbing to the effects of that abuse, so that it was not until the second week of this high caloric feeding that a diarrhea occurred By cutting out the sugar and not changing the food in any other way except to boil the milk, the diarrhea was overcome in four days On June 14, one half ounce of sugar was added to the diet, giving 108 calories per kilogram, or 49 per pound, and we got a gain of 4 ounces, or 0 6 ounce per day, following our period of starvation There was then a continous gain from June 21 to July 27, on food of 118 to 123 calories per kilogram, or 54 to 56 per pound At this time a food containing 132 calories per kilogram or 36 per pound was given, resulting in a diarrhea which was controlled in five days by cutting out the sugar and giving half milk and half water, boiled During this period there was a loss of 2 ounces in weight The sugar was then gradually increased and the child again began to gain on 113 calories per kilogram, or 51 per pound I do not mean to say that overfeeding in calories alone is always the cause of diarrhea, but I think that this case proves that it may be the sole cause in some instances At other times this child digested well the food of the same strength and quantity, and the sugar was never increased by 1½ ounces in twenty four hours, so that that may be eliminated as the cause of the diarrhea in this particular instance

Case 4—Atrophic infant This child, an emaciated, atrophic, *marasmic, decomposition baby, weighing 6 pounds and 14* ounces at 2½ months of age, was white, vomited a great deal, and in bad condition generally It did not gain until the vomiting was overcome by a dilute mixture containing little sugar and of low caloric value The week preceding April 21 it gained 5 ounces, or 0 6 ounce a day on 126 calories per kilo gram, or 56 per pound It will be seen that the food was still dilute, being one third milk and two thirds water, with only 1¼ ounces of sugar The following week increasing the sugar one fourth ounce and the milk 1 ounce raised the calories to 133 per kilogram, or 61 per pound, and there was still a greater gain of 0 9 ounce per day This small increase in the milk and sugar shows how much the calories per kilo gram may be increased by a slight change in the food in small emaciated babies, and therefore how important it is to reckon calories in all our babies, especially the very sick ones, if we do not want to overfeed or underfeed them The following week the food was reduced to 114 calories per kilogram, or 52 per pound, and the baby did not gain at all The next week on 147 calories per kilogram, or 66 per pound, there was a gain of 1 1 ounces per day The next week at 166 calories per kilogram it gained 1 2 ounces per day At this time this unfortunate baby got the whooping cough and vomited so much of the food that the reckon of calories was of no avail, but the food was kept the same throughout the period During this period, however, there was no loss in weight at all The week preceding July 7, the child had 2 ounces of sugar, 22 ounces of milk and 14 ounces of water, making 170 calories per kilogram, or 75 per pound, giving a gain of 1 3 ounces per day It was kept on this high caloric food without any digestive disturbances, the number of calories per kilogram was gradually decreased and there was a gain of 5 pounds and 8 ounces in two months, or considerably over 1 ounce per day The baby was then fat and continued to gain on 110 to 120 calories per kilogram for the rest of the time that I had charge of it

It would be useless to go on citing any more of my twenty five cases that I have followed in this way, because they all show practically the same results The average normal baby will do well on 110 to 120 calories per kilogram I do not consider these figures absolute, but they are at least a good guide if we will also consider the general well-being of the child, the appetite, vomiting, stools and sleep, but I would give more weight to the calories than to the symptoms, as they are far more to be relied on In many cases that I have had it is evident that some were much like Case 3 that I have shown you, in which, if we attempt to increase the calories above the infants' needs, we get these digestive disturbances As we all know, some babies have a tendency to diarrhea, some have a tendency to constipation and some to gastric indigestion Such babies must be kept on the lowest caloric value that will give them a gain in weight

It has long been known that atrophic babies require food of much greater caloric value It has been my experience in my other cases as in the one that I have tabulated that the much emaciated babies will require 160 to 170 calories, whereas those who are only moderately emaciated will require 130 to 150 calories If such babies show a tendency to diarrhea, I would not dare increase the calories so high as I have in the one that I have shown, but would be contented to have a smaller gain on 150 calories

432 East Thirty Eighth Street

ABSTRACT OF DISCUSSION

Dr G R Pisek, New York I take issue with Dr Dennett, placing myself on the side of those men whom Dr Dennett criticized, those who do not believe in the caloric method of infant feeding A study of his charts shows that gain in weight was his guide to influence his variations in the caloric feeding We can all appreciate what there is of value in this method It tells us that a baby will not do well below a certain minimum and that it is in danger over a certain maximum number of calories per kilo

Dr. Fritz Talbot, Boston I have had the opportunity of examining the nitrogen content of cow's milk from different herds of cows and have found that it may vary 20 per cent Furthermore, the amount of fat in the milk of the different herds varied from 3 5 to 4 5 per cent There again was an error of 25 per cent Such figures as these are, therefore, only relative I use the percentages as well as the caloric means of feeding babies I feed the individual baby and not by rule of thumb The well babies that I see in private practice usually need about 120 calories per kilogram of body weight, whereas the babies that I see in hospital clinics need from 80 to 160 calories I believe the individual baby should be fed according to his peculiarities, using all the information we can command, and not by a single method

Dr Charles Douglas, Detroit I think that in considering this subject we should remember the age of these children, and notice that most of them were taken from an early age, we should not apply those figures to the marantic child or the child who has been damaged by feeding While Dr Dennett was talking, I was running over the figures, comparing them with what I have been accustomed to do for many years, that is, so much milk daily per pound of the child's weight Long before I commenced to use calories, which I use only as a check or measure, I had been in the habit of telling the mother that she could expect no gain in weight until she was able to give the baby each day so much per pound of weight As soon as we reach that point we find that the child will begin to gain The figures are exactly the same as I have been in the habit of using right along Whether one figures by percentage or by caloric method, the same conclusion is reached One is really therefore, a check on the other We sometimes see a child who can use only a small percentage of fat, we therefore have to run up high on sugar and protein. It is not well for us to give a diet according to any one system We need all the systems to measure our work and see that the child is given justice

Dr. John L Morse, Boston If I understood Dr Dennett I think that he said we should think in calories and not in percentages I cannot agree with that It seems to me that we should think in both percentages and calories, and if we are going to think of one first, we should think of percentages If we think in calories first, we put the cart before the horse What we really ought to do is to fit the food to the infant's digestion first, and then see if its caloric value is sufficient to cover the baby's needs It seems to me that all these things should be taken into consideration in feeding fat to the individual baby All my hospital charts have lines for calories per kilo just as for weight and percentages I have found that the average baby in the first year needs between 100 and 120 calories in order to gain satisfactorily Babies seldom hold their own on less than 70 calories per kilo, although I have seen babies that gain steadily on 50 calories per kilo I do not know how they do it I have seen others that were underfed on less than 160 calories

Dr H D Chapin, New York The main objection to the use of the caloric method is that it overlooks the principal thing we are after in managing the baby, its growth The caloric method is of value only as a check If we are going to make it the essential thing, we can make up a food of suet and water and get our calories right, but the actual food will be all wrong In the young the main factor is not heat and energy producing food, but growth producing food A system of calories is much more valuable in adults in estimating food values than in babies and young children

Dr R H Dennett, New York I do not mean to put forth this theory of feeding as the only one to go by I was misunderstood in a good many ways I said that we should think in calories as well as in percentages, if we are using the percentage method Of course, everyone recognizes that there is more than one successful method of infant feeding, and we must not have our minds entirely on calories or entirely on any one thing That is evident In regard to Dr Talbot's criticism of the assumption of the fat content, the error in the number of calories per kilo would be very small I started to estimate the error, say that we did differ in our fats 0 5 of 1 per cent, the error in calories for a baby of this age and weight would be very small indeed, because of the matter of division, just as in making up percentage feedings the error in percentages is very small in the end As to Dr Talbot's remarks about the badly damaged child, Case 4 was one of the worst cases I have ever had the privilege of treating

MOVING PICTURE ILLUSTRATIONS IN MEDICINE

WITH SPECIAL REFERENCE TO NERVOUS AND MENTAL DISEASES *

T H WEISENBURG, M D
Professor of Clinical Neurology Medico-Chirurgical College
Neurologist to the Philadelphia General Hospital
PHILADELPHIA

For the past five years I have been interested in the taking of moving pictures of nervous and mental diseases until at the present time I have practically completed my work in both these fields, having about 10,000 feet of film of the various diseases to which this particular specialty lends itself Inasmuch as I have gained considerable knowledge not only in the taking of these pictures, but also in their demonstration and uses, I thought that it would be of some value if I recorded my experiences

I shall first discuss the method of taking these pictures, secondly the various diseases and subjects which can be photographed, thirdly, their availability for teaching purposes, and lastly, their scientific value

TAKING THE PICTURES

Necessarily the greatest objection to the use of this method of teaching is the expense involved, but this can be greatly lessened if advantage is taken of some points In my first attempt the subjects consisted of hemiplegics, diplegics and other patients in whom an attempt was made to demonstrate the gait, station, etc In this I used four or five hundred feet or more for one subject, which was entirely too much, for in the average moving picture machine the rate of illustration is one foot per second and I have found that it is vastly better to show for about a minute a particular gait or patient in whom there is only one thing to demonstrate using about sixty feet, than to exhibit for four or five minutes, because the onlooker becomes tired of seeing the same thing for more than that period I have now adopted the plan of even cutting down that time by using twenty or thirty feet For example, I illustrate the catatonic form of dementia praecox by having the patient appear on the screen for less than half a minute It is vastly better to have many subjects for twenty feet at a time than to show one patient, no matter how good, for a greater length of time In dementia praecox twenty-six patients are used to illustrate the disease

Then again, experience teaches just what is illustrative In one's enthusiasm one may have a subject photographed at length only to find that many of the pictures when thrown on the screen are of no value In addition, a great deal of patience and ingenuity has to be exercised to make the patient perform unconsciously during the time that the pictures are being taken, as in photographing various forms of tics Sometimes, however, it is in the insane patient that the greatest care needs to be exercised I remember that when attempting to take photographs of a number of paranoiacs the camera man came near being assaulted and having his instrument destroyed One curious experience I had with epileptics The superintendent of the colony who very kindly placed his material at my disposal selected eighteen of the many hundred epileptics, every one had fits daily, some of them hourly We placed these patients in the sun with the camera trained on them ready to take a photograph the instant a spasm was manifested, and yet for three hours not a single patient had a sign of a spasm and it was necessary to come the following day before we were able to obtain the photographs Even under these circumstances it was difficult to obtain the beginning of epileptic fits

DISEASES WHICH CAN BE PHOTOGRAPHED

So far all my pictures have been either of the nervous or of the insane Nervous diseases lend themselves particularly to motion photography because of the gaits, tremors, convulsions and different types of tics and spasms In the organic diseases it is easy to illustrate the method of obtaining reflexes, spastic and ataxic gaits, ataxias, tremors, etc I have excellent photographs of all these and also of the different diseases In some, like syringomyelia, in which there is no particular gait or station to be illustrated it is possible to show the patient's atrophy, contractures and trophic symptoms, at the same time outlining disturbances of sensation, which can be marked on the patient with different colored chalk for the different forms of sensation, it is even possible for example in white patients, using charcoal over areas of loss of pain and temperature sensation, to indicate by words within this area in white what particular sensation is lost

---

* Read in the Section on Nervous and Mental Diseases of the American Medical Association at the Sixty Third Annual Session held at Atlantic City June 1912

Of the functional diseases, the various tics, tremors and convulsions can be beautifully illustrated Insane diseases are not so applicable for motion photography excepting in types like catatonia, mania and paresis, and in the facies of the various kinds of insanity

So far as I know no attempt has been made to develop motion photography in the other specialties, but there is no reason why this should not be done In diseases of the eye the different ocular palsies and pupillary changes can readily be shown, while in diseases of the ear it would be easy to illustrate nystagmus from aural involvement These subjects, of course, have a direct relation to neurology

In children's diseases it would be interesting to photograph whooping-cough and meningitis, even the different exanthems could be shown at various stages by color photographs The discussion by the lecturer in demonstrating the pictures materially helps in their appreciation It would be interesting to demonstrate the method of doing lumbar puncture Again, what would be better in the present crusade of public health than to illustrate the right and wrong methods of bathing, dressing and clothing children, and other hygienic factors?

As a matter of fact, moving picture illustrations are already employed by public health bureaus in different states, notably in Louisiana, where the head of that department employed motion picture photography to show the menace of such diseases as small-pox, typhoid fever, etc

In no branch of medicine, with the possible exception of neurology, can motion photographs be of so much value as in bacteriology For some years photographs have been in existence showing the movement, growth and characteristics of different types of bacilli

In general medicine they could be employed to illustrate pyloric spasm, movements of the chest in various heart and lung diseases and the abdominal movements in different diseases of the viscera In surgery and obstetrics it would be easy to illustrate some types of operation One of the first uses of moving pictures in medicine was to illustrate an operation by a French surgeon These pictures were taken about 1902 and were shown in different parts of Europe, eliciting a storm of criticism because the operation was of an obstetric character Unfortunately a type of these pictures has fallen into the hands of unscrupulous individuals and are being shown as motion picture curiosities One of my naval friends on his return from a cruise in South America told me that he had seen such films in a public hall.

VALUE OF MOTION PICTURE FOR TEACHING PURPOSES

To my mind no new development in recent years for the teaching of medicine is of so much value as the use of motion pictures I am aware that some will disagree with me, the only answer I can make is that they have not used such means In my course in nervous diseases to medical students I now regularly employ these pictures If, for example, I wish to discuss epilepsy I first lecture on the disease and then show the reel which contains the different types of fits The reels are arranged according to subjects As a case in point, take the subject of epilepsy How many medical students or physicians are there who have seen typical jacksonian convulsions and different forms of epileptic spasms, such as I am able to show by these pictures? I remember that during my course as a medical student I did not see a fit, and it was not until I became a resident physician at the Philadelphia Hospital that opportunity was given me to observe one

Even in the commoner diseases such as hemiplegia, diplegia and the different types of spastic paralysis, etc, examples of which can always be found in clinics, there is something peculiarly impressive in their being shown by means of motion photography In large cities like Philadelphia where we have the unparalleled advantage of the wards of the Philadelphia Hospital we are always able to produce many examples of this type and I do not deny that it is better for the student to see the actual patient, yet what teacher is certain that the student pays attention when he lectures and shows these patients? On the other hand, the very novelty of moving pictures and the nature of the exhibition compel the student to pay attention I have, for example, shown particular types of patients to students and quizzed about them later Then I have shown other patients by means of motion photography, and have always found that the impression of the latter is much greater and that the student never forgets what has been so indelibly impressed on his visual memory

Is there anything that a teacher appreciates more than to be able to produce at a moment's notice examples of various types of choreas, athetoid movements, astasia abasia, muscular dystrophies, etc? I do not mean to say that I prefer to show motion pictures rather than the actual patient, but I do say that it is well to be able to show patients as they are and again to reproduce them by photographs

USES OF MOTION PICTURES FOR ILLUSTRATIVE PURPOSES

The first attempt to illustrate text-books by motion pictures was that made in my article on "Nervous Diseases" in Anders and Boston's "Medical Diagnosis" In this, hemiplegia, locomotor ataxia, paralysis agitans and spastic gaits are demonstrated I cannot say that I am entirely satisfied with the results I have found since the publication of these pictures that it is necessary to have considerable explanatory legends so that the reader may understand the pictures more fully This, however, is simply a beginning

It is also possible to use motion photography to illustrate a scientific article It occurred to Dr C K Mills and myself that it might be interesting to study emotional expression by this means Our method was first to illustrate normal crying and laughter, using actors for the purpose, who laughed and cried and attempted to do so on one side of the face This was because we had a patient in whom there was loss of emotional expression on one side Then we photographed patients who had either involuntary laughing or crying in such diseases as pseudobulbar palsy, multiple sclerosis, paralysis agitans, astasia abasia, hysteria, chorea, etc The results were surprisingly striking These pictures were shown before the College of Physicians of Philadelphia

SCIENTIFIC VALUE

1 To my mind, the greatest value of moving pictures is to record diseases so that future generations of medical men may have a permanent record

2 In the future we shall be able to exchange films of the different types of the same disease occurring in different countries

3 Rare cases may be permanently recorded In the nervous wards of the Philadelphia Hospital a patient presented the [illegible] symptom [illegible] inability to laugh on one side [illegible] able [illegible] facial muscl[illegible] oth[illegible] died and h[illegible]

This case was the basis of a paper by Dr Mills, under whose care the man was I believe that this is the first occasion in medicine when it was possible to give a history of the case, show the specimen and at the same time illustrate by motion pictures what the patient suffered from during life I quote this only as an example

4 These pictures are of the greatest scientific value because they furnish a new means of detection I have, for example, a photograph of a man with jacksonian convulsions in which the fit starts in the right corner of the mouth and takes in successively the right side of the face, eyes and eyelids and then the muscles of the right hand and then the whole right arm Ordinarily a convulsion of this type is so rapid that there is little opportunity to make extensive observations In the showing of these pictures on the screen the size of the subject is greatly enlarged and it is most interesting to watch the succession of muscular twitching and to show the movement of both eyes eyelids and brow I have never seen a better demonstration of the fact that the unilateral cortical area controls the movements of both eyeballs, but the interesting part is that the eyeball on the side of the convulsion and also the eyelid and brow move more than the corresponding parts on the other side Even, for example, in the taking of such a common sign as the knee-jerk, while we have been aware that there is a perceptible lapse of time between the striking of the patellar tendon and the forward movement of the leg on the thigh, yet this point was never permanently impressed on me until I saw a motion picture reproduction, when it was so obvious that I could not help but notice it, and so it is in many other signs and symptoms As a matter of fact, I have become so impressed with the value of enlarged reproductions of signs and symptoms that I am now in the habit of having all the rare diseases and some of the commoner signs and symptoms photographed

It is my pleasure to state that were it not for the generosity of Mr Sigmund Lubin of Philadelphia it would have been impossible for me to do this work.

2030 Chestnut Street

POSSIBLE TRANSMISSION OF POLIOMYELITIS THROUGH THE DOG

HENRY F LANGHORST, M.D
ELMHURST, ILL.

Among the many theories advanced as to the method of transmitting the contagion in acute anterior poliomyelitis, another may be permissible Those theories which regard dust and flies as the agents of transmission have received the most attention Recently, Rosenau has proved that the stable-fly (*Stomoxys calcitrans*) transmits the virus in the same manner in which the mosquito inoculates its victim with malaria, and his work has been confirmed by Anderson and Frost[1] This is an important step toward the solution of the mystery, but it is not a complete solution for there must be other methods of transmission The disease exists in the winter months in the absence of dust and flies Many cases have appeared in Norway in the winter, and isolated cases spring up in our country from time to time

Basing my contention on the recent findings relative to the transmission of infantile paralysis, and on the knowledge gained from a few of my cases, I wish to advance the following

Poliomyelitis is undoubtedly transmitted to man through more than one intermediary We know one to be the biting fly We also know that the monkey may harbor the infection for some time after being a victim of the disease, and thus be a carrier The biting fly attacks animals and transmits the contagion The dog is subjected to the bite of this fly and may become infected The dog may contract the disease in one form or another, and be an active carrier of the virus for some time

Dogs are numerous in the countries that have suffered most with poliomyelitis, dogs are also more numerous in country districts, where the disease is most prevalent I consider these facts significant, especially in connection with two cases in my practice in which dogs may have been the agents of transmission

REPORT OF CASES

Case 1—The patient, aged 35, was a man of good habits and athletic build He was married and had one child Previous history was negative, with the exception of what I shall mention later He was taken with a severe cough and sore throat about one week before paralytic symptoms appeared He continued his outdoor work of driving a wagon, which was arduous, at that time, on account of the extreme cold and snow The symptoms developed rapidly, he felt weak in his limbs one afternoon, and that evening, after going to the toilet, he was unable to return without assistance I saw him a few hours later and found him completely paralyzed He was gasping for breath and was intensely cyanosed, his legs, arms, abdomen, chest, neck and throat were paralyzed He spoke with great effort and was unable to swallow, his eye muscles were intact and their reflexes were normal. All of his other reflexes were absent, sensation of heat and cold was normal, only slight pain was present on pressure over nerve trunks, he could locate and differentiate between pin pricks with the sharp and the blunt end. The sensorium was clear the patient was in good spirits and had no sense of fear Loud bubbling râles filled his chest and he was continuously making ineffectual efforts at coughing, to try and bring up the mucus that was choking him His vesical and rectal sphincters were tonic. Pulse was 130, temperature 100, respiration 45

By compressing his thorax, and by fixing the diaphragm (using pressure over upper abdominal region) we were able to help him to expectorate considerable mucus of a frothy nature At times the respirations were so labored and the cyanosis so urgent that artificial respiration was resorted to, and kept up for hours at a time Dr Peter Bassoe saw the case, in consultation, and he favored the diagnosis of acute anterior poliomyelitis but also considered the possibility of its being Landry's paralysis On account of the increasing dyspnea, Dr Richter, who had been using an improved pulmotor (made from a vacuum cleaner) was called in, to use his apparatus This was used with good results, and was alternated with the Sylvester method Atropin, strychnin, caffein and camphor were used hypodermatically, normal salt solution was used by rectum by the drop method. The urine contained no albumin, and the examination of the sputum showed many leukocytes, and, among other pus organisms, Pfeiffer's *bacillus* After the third day the patient was able to move his hands and legs slightly, but after five days of severe suffering he became delirious, and on the sixth day died

From the history I learned that the patient's dog had been sick about two or three weeks before, and was unable to stand on its hind legs The patient fed the dog and cared for him The patient remembered that he had a few scratches on his hand and that on one or two occasions, the *dog* licked his hand Flexner has *shown that* the nasal mucosa is one of the points of egress of the virus If the dog had been *inoculated* with the virus at some time and had not immediately contracted the disease he may have been a carrier and not contracted the disease until his vitality was lowered by living in a kennel in the cold weather The dog could have inoculated his master with the secretions from his nose and mouth

---

[1] Transmission of Poliomyelitis by the Stable-Fly (*Stomoxys calcitrans*) editorial The Journal A M A Nov 2, 1912 p 1627

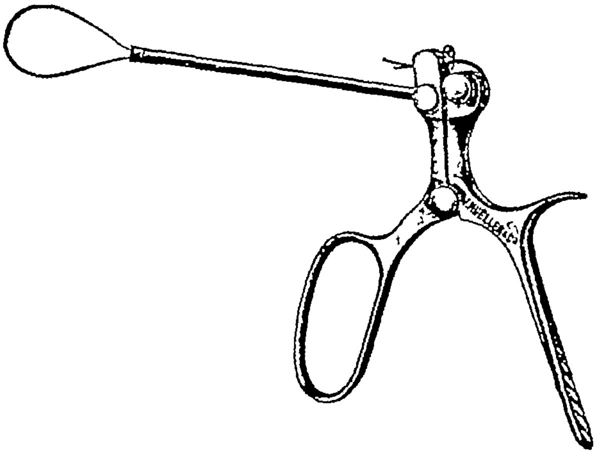
Case 2—The patient, a boy of 6 years, was brought to my office Aug 9, 1912, to be treated for a bite inflicted by his pet dog I saw him about an hour after the injury and applied a 1 per cent solution of formaldehyd and then used tincture of iodin The wound healed nicely The boy then accompanied his parents on a trip to Canada, leaving here August 23 While in Canada, on the 30th, the boy had a little fever and complained of his neck being stiff The family immediately returned to Elmhurst, arriving here September 1 I saw the boy at this time, he had a slight fever (temperature 101), and did not complain greatly He had pain in the back of his neck and in his head, and he felt weak His reflexes were present and he was able to stand and walk When I saw him the next morning he was paralyzed in all of his extremities, the chest and neck muscles were also involved The reflexes were absent Dr Abt saw the patient with me and called it infantile paralysis Dr D'Orsay Hecht also saw him a few weeks later and agreed to the diagnosis The boy is gradually recovering

---

A NEW TONSIL-SNARE

W Likely Simpson, M D, Memphis, Tenn

The snare shown in the accompanying illustration consists of a large and a small tube and a handle set at a right angle to the tubes The small tube is attached to the posterior shank of the handle and is inserted within the large tube, which is attached to the anterior shank of the handle A small wheel is attached with the small tube to the posterior shank of the handle Both tubes are so attached to the shanks that they can move up and down As the instrument is opened the small inner tube has a tendency to move upward and the large outer tube downward, but both working together make a tube which moves neither up nor down



The wire sling, instead of being fixed to the small inner tube as in other snares, goes entirely through both tubes, around the small wheel at the posterior end of the small tube and forward to the attachment of the large tube with the anterior shank of the handle, doubling itself, where it is fastened with a screw This is a most important feature of this snare, since the instrument can thus be made quite small, it will, however, close entirely over a wire loop larger than would be necessary for any tonsil I would suggest the freeing of the tonsil from adhesions to the pillars or adhesions in the supratonsillar fossa, but I do not consider it necessary to dissect the tonsil from its normal bed in any way, when it is freed from adhesions, the tonsil and its capsule can be pulled through the snare without harm to the pillars If there are no adhesions, the tonsil can be entirely removed in its capsule by pulling it well through the snare shutting down on the base

The advantages of this snare are It is sufficiently powerful to remove any tonsil, it has a handle with a powerful grip set at a right angle to the tubes of the snare, which is to be preferred to a snare with a straight pull backward in the direction of the tubes One can exert the whole power of the hand if necessary, which is impossible in the ordinary snare The tubes being movable up and down, the instrument can be opened and closed with ease

A COMPRESSED AIR OINTMENT APPLICATOR AND DISTRIBUTOR

Daniel W Layman, M D, Indianapolis
Attending Oto Laryngologist Indianapolis City Hospital and Indianapolis Orphan Asylum

Ointments as remedial agents to the nasal mucosa have not been extensively used, the nasal douche or spray being the more popular form of application, chiefly because remedial agents can be readily and easily applied in a fluid state Ointments have been used principally to protect the skin and mucous membrane at the entrance of the nostrils from being excoriated by irritating nasal discharges Occasionally they are used to protect the margins of a perforating ulcer of the septum or to stimulate granulation tissue to a more healthy action It is certain that a greater quantity of active agents can be delivered to the nasal mucous membrane and can be retained for a longer period in ointment form than in the fluid state

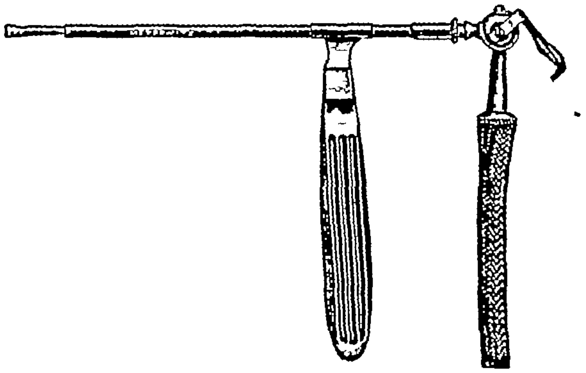

Fig 1—Compressed air ointment applicator and distributor

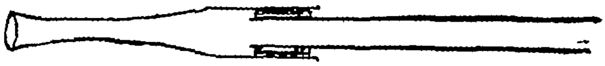

Fig 2—Glass tip fitted firmly over end of cannula by rubber tubing

The objection to the use of ointments in the nose is the crude and inefficient methods of application When pressed from a conical tube, the ointment is not carried beyond the anterior nasal chamber When applied with a cotton wound applicator (the method mostly used by rhinologists), the ointment is difficult to apply, as it adheres to the cotton closer than to the mucous membrane At best, the ointment can reach only a limited area in the upper nasal chamber, and cannot reach the greater part of the ethmoid region and the area included in Ballenger's "vicious circle"

For the application of ointments to the nasal mucosa I have devised an instrument by means of which the ointment is applied and distributed by compressed air This instrument (Fig 1) consists of a metal cannula with a handle, or holder, and a glass tube The opening of the cannula at the handle end is made to receive the tip of a compressed air cut off In the latest model (Fig 2), a glass tube is made to fit snugly over the other end of the cannula by means of a piece of rubber tubing The tube is about 2 inches in length, and is made of glass for cleanliness and in order to gauge accurately the amount of ointment to be used The tip is flaring [illegible] like the end of a blunderbuss With this [illegible] application of ointments to the nasal mucosa [illegible] dure [illegible] of many of the small [illegible] t into of the glass tube When the ointment tube is thus inserted, as much of the ointment as is desired is deposited in the glass tube by pressure with the fingers A blast of air of 15 or 20 pounds' pressure is passed through the cannula, from which it shoots the ointment to the parts directed, applying and distributing it over a considerable area of mucous surface and into small recesses or openings where the cotton wound applicator cannot reach

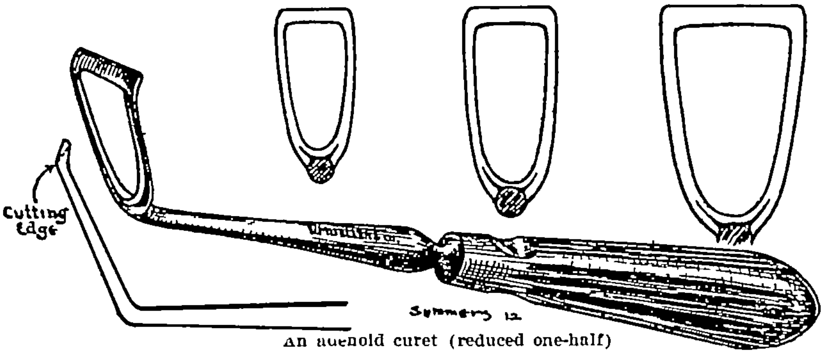
Nasal medication in ointment form is becoming more popular with rhinologists Text books on diseases of the nose and throat recommend ointments as valuable remedial measures If any instruction is given as to application, it runs as follows "Insert the elongated tube into the nostril and press slightly, or apply on pledget of absorbent cotton in the usual way"

The instrument I have described has been worked out to improve on this old method

AN ADENOID CURET

Greenfield Sluder, M D, St Louis

The accompanying pictures show the form of a curet the cutting edge of which is further removed from the shaft than in any curet at present made, so far as I know I designed it for use in throats (1) in which the distance between the hard palate and the rostrum of the sphenoid is much greater than the average and (2) in which there is a considerable excavation of the space between the basilar process of the occiput and the atlas When this space exists it may harbor a considerable amount of lymphoid tissue which cannot be removed by any of the curets of the usual form The upright portion of this one is tilted backward to an angle of 120 degrees, which permits it to reach upward and backward into this space In using it for this purpose I begin by holding the shaft against the upper incisors and hard palate



An adenoid curet (reduced one-half)

I have found that this instrument frequently serves well in removing tissue from the fossa of Rosenmüller I have three sizes

3542 Washington Avenue

The Triumph of Hygiene—For centuries man has tried to turn back, or at least to control disease by cure, yet knowing since the days of the creation of the mythologic Hygeia that prevention was the rational course At no period in history has this truth been more forcibly shown than in the last quarter century by the triumph of hygiene over yellow fever In connection with that disease therapeutics bore no burden Not a single medicine in all materia medica had the least effect Prevention, and it alone, has abolished yellow fever And this broad application of hygiene to the masses brings wholesale health And it should be noted that, as with typhoid fever, the prevention of one case prevents three cases of other diseases Business has profited greatly by this triumph of hygiene over yellow fever, and government and morals and all other elements of civilization also—J N Hurty in *Am Jour Public Health*

Therapeutics

DISTURBANCES OF THE HEART

(Continued from page 2257)

TREATMENT OF BROKEN COMPENSATION

The consideration of this subject will include the following topics

A. Hygiene
B Diet
C Elimination
D Physical measures
E Medication
    1 Cardiac Tonics Digitalis, strophanthus, caffein, strychnin
    2 Cardiac Stimulants Camphor, alcohol, ammonia
    3 Vasodilators Nitrites, iodids, thyroid extract
    4 Cardiac Nutritives Iron, calcium
    5 Cardiac Emergency Drugs Ergot, suprarenal active principle, pituitary active principle, atropin, morphin, and also some of the drugs already mentioned.

A HYGIENE

Of all treatment for broken compensation or dilated heart nothing equals rest in bed Sometimes it is the only treatment that is needed The rigidness of this rest, the length of time that it should endure, and the period at which relaxation of such rest should be allowed depend entirely on the individual patient, no rule can be established Most of the symptoms must disappear before exercise is allowed Perhaps a not infrequent exception to the rule is when cardiac weakness, generally a myocarditis, develops in a patient after 50 It is not always wise to keep such a patient in bed, he may be rested and his exercise greatly restricted, but sometimes it is difficult to get him out of bed if he is kept there any length of time

Fresh air, sunlight and anything else that makes the bedroom attractive and cheerful are essential and will aid in the recovery The kind of nurse that is needed, trained, untrained, or a member of the family, and the amount of company or entertainment that the patient shall have must be entirely decided for the individual patient The patient must be distinctly individualized and the proper measures taken to give mental and physical rest, to prevent excitement worry, melancholia and depression, and to improve the general nutrition of the body as well as the condition of the heart

Each occurrence of broken compensation in valvular disease causes another attack of cardiac weakness to occur with less excuse than before, and several serious attacks of broken compensation mean before long the loss of the heart muscle's ability to recover, so that permanent dilatation occurs

B DIET

The food given should be just sufficient for the needs of the body, the patient should not be overfed or underfed Any large bulk of food or liquid should not be given Pressure on the heart causes discomfort and is therefore inadvisable Food that causes flatulence should be avoided Theoretically the patient should receive a little meat, an egg or two, cereal or bread, a small amount of simple vegetables, a little fruit, often milk, a sufficient amount of non-effervescent water, perhaps a cup of chocolate or cocoa, a simple dessert, sometimes ice-cream, in other words, a varied, limited diet containing all the elements that are necessary to good nutrition The diet should be varied from day to day to encourage the appetite

It has for several years been recognized that a salt-free diet in dropsies due to disease of the kidneys is a valuable aid in causing absorption of such exudates and of preventing greater exudations For this reason a salt-free diet is often ordered in dropsies occurring in valvular disease Its value, however, is not so great as in kidney lesions, and if it causes hardship to the patient it should not be continued rigorously On the other hand, large amounts of salt should of course be interdicted

A most valuable aid in dropsies due to heart deficiencies is the so-called dry diet, which means that as little liquid as possible should be taken in order that the patient's blood may resorb the exudate in the tissues and not have the blood-vessels filled or overfilled with liquid from the gastro-intestinal tract When dropsy is present, or even when serious pendent edemas are present, the patient should drink as little liquid as possible with his meals and between meals should sip water rather than drink a large quantity of it This is one of the reasons that a large milk diet, even with kidney disturbance due to cardiac lesions, is generally inadvisable With cardiac or general circulatory weakness a large amount of liquid to flush out the kidneys and the whole system, so long ordered for all kidney defects or mistakes in metabolism, is a serious mistake

Whether it is better to give three or four small meals a day or to give a small amount of nourishment every three hours during the daytime must again depend on the individual and his ability to digest without fermentation and putrefaction or discomfort As previously urged, not too much fluid, even milk, though it digest perfectly, should be given, as the greater the amount of fluid the greater the amount of work thrown on the heart

C ELIMINATION

A patient who has developed cardiac incompetency has always imperfect elimination The skin, bowels and kidneys do not act sufficiently or well The circulation in the skin is sluggish The bowels are generally constipated, or there is diarrhea of the fermentative type The amount of urine excreted is generally insufficient and likely to be concentrated and show various signs of imperfect kidney elimination Therefore hot sponge baths, with perhaps warm alcohol rubs, are daily necessary Gentle massage, generally in the direction to aid the circulation, will benefit the skin If the skin is dry or in places scaly, oil rubs are of great benefit

The bowels must be moved daily and sufficiently, but there should be no watery purging allowed or caused If it seems advisable in the beginning of the treatment to give a calomel purge, it should be done, but such purging should ordinarily not be repeated, although occasionally a grain or two of calomel, combined with the vegetable laxatives needed, may act perfectly and without causing depression Saline purgatives, or even laxatives, are generally not good treatment when there is cardiac weakness The bowels should be moved by vegetable laxatives, as aloin, cascara sagrada, or some simple combination of either or both of these drugs

Diuretics are often not satisfactory in cardiac insufficiency The cardiac tonics that are given the patient, and the improvement of the heart from the rest in bed generally start the kidneys to secreting properly A diuretic administered when the kidneys are suffering passive congestion from cardiac insufficiency does not generally act, and is therefore useless If digitalis is administered, it will act as a diuretic, if caffein is deemed advisable, that will act as a diuretic Squills may be administered, if it seems best If for any reason the kidneys secrete less urine and become insufficient, the diet should quickly be reduced to a small amount of milk, cereal and water, and hot baths and local heat to the back should be inaugurated

D PHYSICAL MEASURES

Hydrotherapy is often of great value in restoring compensation by improving the surface circulation Sponging with hot, tepid or cold water, as indicated, will increase the peripheral circulation and the normal secretions of the skin.

When compensation is perfect, in valvular lesions, more or less frequent warm baths are advisable, and often relieve the heart by equalizing the circulation Cold sponging in the morning may be advisable, but may do harm when there is high tension, warm, not too hot, baths are of value Anything is of value that improves the peripheral circulation and prevents the extremities from being cold

The value of the Nauheim or other carbonated baths is perhaps often a question They have seemed in many instances to aid in improving compensation in such patients as have been able to go abroad for the treatment On the other hand, so many other regimens are ordered and inaugurated for these patients at these "cures" that it is hard to decide how much benefit the baths have really done At home the artificial carbonated or carbonic acid baths do not seem to be of great value Baths and bathing can do harm, and the decision as to which hydrotherapeutic measure shall be used and the extent to which they shall be used can be made only after careful observation of the patient by the physician

Gentle massage while the patient is in bed is of undoubted value, more vigorous massage is later often of value, provided there is no arteriosclerosis As the patient grows stronger and the circulation improves, the muscles are kept in good condition during the enforced rest by massage When properly applied, it promotes not only the venous return circulation, but also the lymphatic circulation, it often removes muscle aches and muscle tire and restlessness

While the patient is still in bed, various resistant exercises are of value, and should be begun These tend to prepare the patient for his later greater activities, in other words, the surprise to the heart when the patient begins to sit up and walk is not so great if he has previously taken these exercises. Later, when the patient is ambulatory he should by gradual gradation walk a little more about the house and take a few steps of the stairs at a time, until gradually he is able to mount the whole flight Later he should take outdoor exercise, and when his heart has become compensated for ordinary work, he should be given gradually graded hill-climbing with the idea of increasing his reserve cardiac power If it is found that these increased exertions cause him to have pain or a more rapid heart than is excusable, even after persisting for a few days, the attempt to increase this reserve power of the heart should [illegible] There is probably, at least at that [illegible] le myocarditis, although the [illegible] still more Pushing it to overexertion, however, will not accomplish improvement

Graded exercise was first used scientifically by Oertel and Schott, and has been for years designated by their names Modifications of their rigid rules are generally advisable

E MEDICATION

1 *Cardiac Tonics*.—Digitalis There is no drug that can take the place of digitalis in loss of compensation in chronic valvular disease It acts specifically for good, and it has its greatest success in the valvular lesions that cause enlargement of the left ventricle, on which it acts the most intensely It also acts for good on the right ventricle It has but little action on the auricles This is simply a question of muscle, the part that has the greatest amount of muscle will receive the greatest benefit from digitalis, and the parts that have the least, the least benefit The heart muscle is somewhat similar to other muscles, when we attempt athletic improvement in any muscle of the body we "train" by stimulating it moderately at first, and are careful not to overwork it, the object, then, is to train the heart muscle For this reason large doses of digitalis should ordinarily not be given to overstimulate suddenly an overworked and weak heart While in some instances it has been declared that digitalis should be rapidly pushed to the full extent and then dropped for a time, careful experience shows that this method is often not tolerated, sometimes does positive harm, and has at times seemed to hasten death

Another valuable activity of digitalis is in slowing the heart by action on the pneumogastric nerves A dilated heart has lost more or less of its regulating mechanism, this is the cause of its irregularity and its increased rapidity The action of digitalis in slowing the heart, giving it a longer rest, and preventing it from acting irregularly is of great value This prolonged rest or diastole of the heart allows the circulation in the coronary arteries to become normal, and the nutrition and muscle tone of the heart improves Digitalis also increases the blood-pressure, not only by improving the activity of the heart, but also by causing some contraction of the arterioles This feature of digitalis action in arteriosclerosis renders its use sometimes a question of careful decision The dose of digitalis under such a condition should not be large It may be indicated, however, and may do a great deal of good, and it does not always increase the blood-pressure

All preparations of digitalis deteriorate, and it is difficult to obtain from most druggists active preparations of digitalis, unless they have been freshly prepared If the patient is sufficiently ill to require the best action of digitalis, an active preparation should be obtained It was long supposed that the infusion presented activities that could not be furnished by the tincture of digitalis This seems not to be true The greater value of the infusion is generally because it is freshly made and active the tincture that had been used previously in a given case was old and useless, also most physicians give a larger dose of the infusion than they ever do of the tincture Owing to the uncertainty of the value of the digitalis leaves found in the various drug shops, however, and to variations in the preparation of the infusion, it is generally better to use a tincture of known character The beginning dose of such a tincture should generally not be more than 5 drops, and it should not be repeated more frequently than once in eight hours It is generally advisable, in two or three days, to increase this dose to 10 drops once in twelve hours, later perhaps to 15 drops twice a day, and still later to 20 drops once a day This amount may then be decreased gradually, if the action is satisfactory In other words, enough should be given to procure results, and then the dose should be brought down to what seems sufficient and best, administered once a day The frequency advised in the administration of this drug is because it is eliminated slowly Its greatest action develops a number of hours after it has been taken, and then the action lasts for many hours, the administration of digitalis once in twenty-four hours is perfectly satisfactory for many patients, and more satisfactory than any more frequent administration On the other hand, some patients do better on a smaller dose once in twelve hours This frequency is always sufficient

The most reliable preparation that we can obtain is probably digipuratum This may be obtained in tubes of twelve tablets, and is a very active preparation The advice has been given for patients with loss of compensation to receive four tablets the first day, three the second, three the third, and two the fourth day This, however, is generally an overdosage The most that should generally be given is one of these tablets once in twelve hours, and many times a most splendid action from their use occurs when but one tablet a day is administered

Another reliable preparation is digitol, a fat-free tincture of digitalis which is physiologically standardized and which bears on each package the date of manufacture The dose is 0 3 to 1 c c (5 to 15 minims)

Digitalinum, one of the active principles of digitalis, is not very satisfactory It may be given hypodermatically, but often causes irritation, and the proper dose, and its value are likely to be uncertain

Digitoxin, another active principle of digitalis, has been declared by some investigators to be harmful, and to be likely to cause serious disturbance of a damaged heart Other investigators have stated that it acts for good A preparation termed digalen, said to contain "amorphous digitoxin," has been largely used, and many clinicians have thought, with value The dose suggested by the instructions and by the medicine-dropper furnished with the sealed package is generally too large While it sometimes undoubtedly causes cardiac pain, so may every preparation of digitalis Digitoxin, and therefore probably this preparation, do not represent the whole value of digitalis, and in broken compensation digitalis itself, or some preparation embodying the majority of its activities, should be given Digitoxin, however, is often valuable in conditions of cardiac debility or slight weakening in patients who do not have dilated hearts or edemas The most satisfactory dose of digalen is from 5 to 10 drops once or twice in twenty-four hours

Digitalis should not be used when there is fatty degeneration of the heart, it should ordinarily not be used when there is arteriosclerosis, and very rarely, if ever when it is decided that there is coronary disease Whether digitalis should be used when there is considered to be much myocardial degeneration is a question for individualization One can never be sure that the heart muscle is so thoroughly degenerated that no part of it would be benefited by digitalis when compensation is lost, therefore, many times, especially if other drugs have failed, small doses of digitalis should be tried, to see if the heart will respond Large doses or frequent doses would be contra-indicated

The signs of overaction of digitalis are nausea, vomiting a diminished amount of urine, a tight, band-like feeling around the head, perhaps occipital headache and coldness of the hands and feet, or frequently of one extremity only, combined with a feeling of numbness The pulse is generally reduced to sixty or less a minute Such symptoms require that digitalis be immediately stopped They are the primary signs of cumulative action

While many patients with ordinary dosage of digitalis may take the drug for months and years without ever showing cumulative action, other patients show this, effect quickly They are likely to be those in whom the kidneys are not perfect The signs of such undesired action may develop slowly, as suggested by the symptoms just enumerated, or they may develop suddenly The pulse becomes rapid and irregular, the heart action weak, there is severe backache in the region of the kidneys, a greatly diminished amount of urine, or even partial suppression, severe headache, vomiting, cold extremities and shiverings

The treatment of such an undesired behavior of digitalis is, of course, to stop the drug immediately, give saline laxatives, hot sponging or hot baths, nitroglycerin and perhaps alcohol

Strophanthus Strophanthus cannot be compared with digitalis, except when the glucosid strophanthin, is administered subcutaneously or intravenously Strophanthus is given either in the form of the tincture, or as strophanthin It has been shown that in neither of these forms, when the drug is administered by the stomach, is the muscle of the heart or the blood-vessels much acted on In other words, compensation could not be restored by strophanthus In emergencies of serious cardiac failure strophanthin intravenously has been shown apparently to save life It acts quickly, and its power of stimulating the heart and contracting the blood-vessels lasts for many hours It is rarely, however, that the dose should be repeated, and then not for twenty-four hours, but during that twenty-four hours the patient may be saved until other drugs which act more slowly have been absorbed, or perhaps until the emergency has passed

There are many, however, who believe that they obtain considerable value from the tincture of strophanthus, and there seems to be no doubt that although strophanthus, given in the form of the tincture and by the mouth, may not increase the muscle power of the heart, it many times acts as a satisfactory cardiac sedative Under its action the patient becomes less nervous, the heart often acts more regularly, and the low blood-pressure may improve In other words, we should not be quite ready to discard the internal use of the tincture of strophanthus

The tincture of strophanthus readily deteriorates, and the preparation ordered should be known to be a good one

Caffein This should not be given or allowed, even in the form of tea or coffee, to patients who have valvular lesions with perfect compensation, as it is a nervous and cardiac stimulant and may cause a heart to become irritable It raises the blood-pressure slightly, acts as a diuretic, and hence is often of great value when used medicinally It should be ranked as a stimulotonic to the heart It increases its activity, but gives it a little more strength It will rarely slow a rapid heart, it will often stimulate a sluggish, slow heart, it may increase the irritability of an irritable heart As it is a cerebral stimulant, it should not be given late in the afternoon or evening, as it may prevent sleep

The most frequent form of caffein used is the citrated caffein The dose is 0 1 gm (1½ grains) two or three times in the early part of the day, or 0 2 gm (3 grains) once or twice during the morning A cup of coffee may be given the patient medicinally, as a substitute for the drug, an ordinary cup of strong coffee containing between 2 and 3 grains Other preparations of caffein may be selected if desired, or a soluble preparation may be given hypodermatically

Caffein is indicated if digitalis is contra-indicated or does not act satisfactorily, and the patient is not nervously excited, but perhaps is stupid or apathetic, and also when diuresis is desired

Strychnin This is a valuable stimulator and heart tonic when properly used It promotes muscular activity of the heart much as it promotes all muscular activities It awakens nervous stimuli and nervous transmissions to normal in all sluggish nerve functions If for these reasons the heart acts more perfectly, and the nutrition of the heart muscle improves it acts as a cardiac tonic Many times, by improving the action of the heart, and also by the action of the drug on the vasomotor center, the pressure in the peripheral circulation may be increased On the other hand, strychnin *in the low blood-pressure of serious illness, such as pneumonia, by no means always raises the blood-pressure*

It should not be forgotten that strychnin is a general nervous stimulant, especially of the spinal cord If it makes a nervous patient more nervous, or a quiet patient restless and irritable, it is acting for harm and should be stopped, just as caffein under the same conditions should be stopped Strychnin may cause diminished secretion of the skin This is not frequent, but it does occur It may prevent the patient from sleeping If such be the fact, strychnin is not acting for good in a patient who has cardiac weakness

Strychnin is a much overused drug It is now given for almost everything and during almost every disease It is true that the administration of strychnin is largely due to the evolution of the age in which we are now living We have ceased to purge and bleed and sweat, and to give large doses of aconite or veratrum viride, we have ceased to starve the patient too long, we have ceased to load him with alcohol to the point of circulatory prostration, and we have recognized that he must be braced from start to finish, strychnin is the drug that has been used for this purpose, and, as above stated, overused Strychnin given too frequently or in too large doses for a laboring heart can prevent its proper rest, the diastole is shortened and the relaxation of the heart is incomplete, its nutrition suffers, or even irregular and fibrillary contractions of a weak heart may apparently be caused While a large dose of strychnin, even to one-twentieth grain hypodermatically, may be used once in serious emergency when it is deemed the drug to use, a dose larger than one-thirtieth grain hypodermatically is rarely indicated, the frequency of such a dose should seldom be more than once in six hours, and a smaller dose of strychnin may act more satisfactorily

Strychnin is indicated when the heart is acting sluggishly and the contractions seem incomplete and when digitalis either is not indicated or is not acting perfectly Small doses of strychnin may aid such a heart during the administration of digitalis In many instances in which digitalis is contra-indicated, strychnin is of marked value This is typically true in fatty hearts, and may be true in arteriosclerosis, in which it of [illegible] not [illegible] the blood-pressure at all

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

535 Dearborn Avenue . . Chicago, Ill.

Cable Address . . Medic, Chicago

Subscription price . . Five dollars per annum in advance

[*For other information see second page following reading matter.*]

SATURDAY, DECEMBER 28, 1912

The large amount of space required for the Index in this issue necessitates the omission of some departments and the abbreviation of those used.

THE INDEX

The fifty-ninth volume of The Journal is indexed in this number. As usual, the Index covers everything that has appeared in The Journal, including the titles and abstracts from current medical literature. As the latter have been chosen for their timeliness and importance, a perusal of the Index will show at a glance medical progress during the last six months, but the practical side of the Index is its greatest value to most physicians. A glance at some of the subjects which are allotted considerable space will show this. There are 100 subtopics under anesthesia and anesthetics. Cancer and its treatment are considered in 174 references, grouped under 150 subtopics. There are 195 subtopics under children and 158 under infants, the latter including the diarrhea of infants, infant-feeding, hemorrhage of new-born infants, pyelitis, scorbutus and tuberculosis in infants, etc. Of the 30 subtopics under diabetes mellitus, 10 refer to articles on the dietetic or therapeutic management. There are nearly 90 subtopics under fracture and its treatment. Under obstetrics and the allied subjects of labor, eclampsia, pregnancy, placenta and cesarean section, there are 275 subtopics. Under syphilis there are over 130 subtopics, under tuberculosis over 320, under typhoid, about 80. As indicated in connection with cancer, the number of articles is much greater than the number of subtopics.

Practically all the foreign journals listed will be lent by The Journal to subscribers and members within the United States on receipt of an addressed envelope and postage to cover the expense of mailing. It is understood that journals will be sent back in seven days. Domestic journals, of course, can be obtained direct from the publishers. Thus the journals indexed are accessible to the general practitioner.

The Index consists of two parts — an author and a subject index. Under "Authors" appear the names of all who have contributed articles to The Journal or to any other medical journal listed in the current literature, as well as the names of those whose papers are abstracted in the medical society reports in The Journal. Under "Subjects" will be found complete references to all reading-matter in The Journal and references to the original articles in all domestic and foreign journals listed, arranged under the subject of the article with double entry when necessary and with numerous cross-references to facilitate the use of the Index. The figures in bold-faced type refer to reading-matter in The Journal.

For the convenience of those who wish a practical working guide in handy form, the Index is published separately under the title "Guide to Current Medical Literature." Physicians who have files of The Journal, either bound or unbound, will find this a convenience.

FALLACIES IN RELATION TO MICROORGANISMS AND FEVERS

We have already called attention to the assertion of Drs. Hort and Penfold of the Lister Institute in London that the febrile temperatures so commonly recorded after subcutaneous injections of various sorts are due to pyrogenic contaminations of the solvents used.[1] It was remarked that this fact — if it be a fact — must be taken into account in all further considerations in the field of experimental investigation or practical therapeutics where this method of injection finds an application. In the current conception of certain types of fever production the essential feature is the introduction or absorption of disintegration products of alien protein or foreign protoplasm such as that of microorganisms. If the studies and practices in this field have regularly been confused by the unsuspected injection of various substances which are contaminations of the common diluents employed, such as water or saline solution, fallacies have crept in and should be generally understood. The sterility of the liquids used affords no guarantee of the absence of the alleged substance, since it is described as a heat-stable pyrogenic substance.

More recently the same investigators[2] have directed attention to still other factors which, they believe, have introduced fallacies into much experimental inquiry on the fever produced by microorganisms. One of these relates to the volume of the diluent used. Thus if a fraction of a culture, non-lethal when given alone, was injected in a volume of water equivalent to from about a hundredth to a twenty-fifth of the body weight, death often ensued in an hour or two. Water alone, used in comparable quantities, did not cause death. Again Hort and Penfold report decided differences in the results of injections of extracts of certain bacteria depending on the use of physiologic saline (0.85 per cent sodium chlorid) solution in place of water. Finally, they refer to the masking of effects by undue dosage.

---

[1] Fevers Following Subcutaneous Injections, editorial, The Journal A. M. A., Dec. 14, 1912, p. 2156.

[2] Hort, E. C., and Penfold, W. J.: Microorganisms and Their Relation to Fever, Jour. Hyg., 1912, xii, 361.

There is so much experimental work in progress relating to the pyrogenic effect of extracts of dead cultures of microorganisms, and the factors involved appear so pertinent in relation to the experimental and practical use of vaccines, that it appears timely to call attention again to what is here involved. As Hort and Penfold contend, if it is an advantage in the treatment of an established infection to occasion fever by the injection of impure vaccines, standardization of the pyrogenic content of a vaccine will in the future be no less necessary than that of its bacterial content.

The English writers insist that no injection experiments dealing with so-called protein fever, endotoxin fever, anaphylactic fever or bacterial fever can stand unless based on clear recognition of the numerous sources of fallacy which they have named. We have no experimental information respecting the validity of their assertions or the real existence of the alleged adventitious pyrogenic substances. Perhaps some of our readers are prepared to furnish authentic evidence on the subject under review. The far-reaching points involved are too important, however, to be dismissed without adequate critical review.

COMMERCIAL HASTE VERSUS SCIENTIFIC CONSERVATISM

Business demands promptness; science can afford to wait until its conclusions are tested and proved unquestionable. An example of business haste is furnished by an announcement made April last at the International Congress on Tuberculosis. Countess von Linden and her co-workers, Professor Meissen and Dr. Strauss,[1] read papers at the Congress describing a new remedy for tuberculosis, the result of work carried out under the advice and direction of the late Professor Finkler. The authors styled the new method a "chemical therapy of tuberculosis," suggesting a relation to the *therapia sterilisans magna* of Ehrlich; it employs a combination of iodin with methylene-blue, and a combination of copper with lecithin. It was also announced that the remedy would be put on the market "as soon as possible" by a certain German dye-firm.

Professor Selter, a former assistant of Professor Finkler, has now published an article[2] which throws some light on the hasty manner in which the reports of these so-called researches were prepared. Selter asserts that he was entrusted by Professor Finkler with the carrying out of these experiments, which were afterward taken over by the Countess von Linden. Selter then carried on some work under his own initiative and, contrary to the results of von Linden, found that no marked difference was observed between the treated and the control animals. His clinical trials also showed no decisive benefit from these remedies. Selter says that he protested to Countess von Linden and her colleagues against such premature publicity as they contemplated, feeling that the work had not yet reached a stage that made publication advisable. They refused to wait, however, and in their papers made no reference to Selter or his work. It seems as if ordinary prudence would have led these investigators, when requested not to publish their premature conclusions, to give at least some indication that other experimental trials had not been so favorable as those which they presented. The motive which prevented their doing so cannot be stated with certainty, but the connection with a powerful commercial firm is, without doubt, a strong temptation to optimism in such research. The close connection of this investigation with the firm previously referred to is shown by a recent article of von Linden,[3] in which she states that the analyses of the organs of her experimental animals were performed in the firm's laboratory. Apparently the firm is interested in the production of a new proprietary, and business interests demand that it be put on the market "as soon as possible."

In contrast with this business-like haste, the patient work and conservative conclusions of Selter appear to be characteristic of the true scientist, who regards time as nothing in comparison with the establishment of truth — not to speak of the humanitarian, who will hesitate to rouse without reason the often disappointed hopes of myriads of unfortunate consumptives, and who rather than do this will sacrifice some of his claims to priority in scientific discovery.

Current Comment

PROFESSOR MINOT IN BERLIN

The system of exchange of professors between some of the European and American universities inaugurated several years ago has already been productive of good results; it not only has brought to our shores some of the continental leaders of thought, but has also spread abroad a more favorable conception of the work of American teachers. It is singularly appropriate that the Harvard exchange professor for the current year at Berlin, the well-known embryologist Dr. Charles Sedgwick Minot, has emphasized the desirability of acquainting our German colleagues with the progress which has been made in this country in recent years in the pursuit of certain fields of science with which he is eminently familiar. In his introductory lecture at Berlin, Professor Minot stated that he regarded himself in a sense as a representative of science in America and accepted the duty of reviewing the contributions made by his fellow countrymen in recent years to the domain of anatomy and embryology. He pointed out that in several fields of research American investigators have taken a leading part, for instance, in the study of the origin of the lymphatic system, the interrelation of the nerves and the brain, the problems of cytomorphosis, and the origin of sex Professor Minot also reviewed the peculiar, complex and varied organization of our American universities — a topic naturally confusing to the foreigner, he sketched the rise of the research institutions, commented on the place of collegiate education in our national life, and appropriately acknowledged the debt which America owes to Germany for encouragement and inspiration in the pursuit of science With Professor Theobald Smith and Professor Minot representing us in Berlin in successive years as ministers to the court of German science, American medicine can feel a just pride in its status there

INHALATION OF DUST, AND TUBERCULOSIS OF THE LUNGS

On exposing normal guinea-pigs to the inhalation of various kinds of dust Cesa Bianchi[1] found that more or less inflammation of the bronchial mucous membrane and enlargement of the peribronchial lymph-nodes would result, but that otherwise the conditions in the exposed were quite like those in normal animals When guinea-pigs exposed to dust were infected with tubercle bacilli, however, they almost without exception perished from tuberculosis, the process running a much more rapid course, and the pulmonary involvement being much more pronounced in the exposed animals than in the control animals The results did not seem to be modified by different kinds of dust There developed in some of the animals an extensive cavity formation in various parts of the lungs, especially those in which the tubercle bacilli were introduced through the air passages It appears then that inhalation of dust in the guinea-pig reduces the resistance of the lung tissue to tubercle bacilli so that it becomes a more favorable soil for their development It is well known that in normal guinea-pigs it is difficult to produce a tuberculosis which is predominatingly localized in the lungs, in animals exposed to dust, however, this seems to take place readily, especially when the infection is introduced by way of the respiratory passages These results corroborate the results of clinical experience and statistical study to the effect that the inhalation of dust of various kinds is harmful and favors directly the development of pulmonary tuberculosis

THE MODE OF INFECTION IN EPIDEMIC POLIOMYELITIS

The theory of the nasal route as one path of the virus of epidemic poliomyelitis to and from the body appears at present to be fairly well justified It seems probable that the nasal mucosa is one at least of the sources of infection to other organisms as well as a means of the entrance of the virus into the infected organism The experimental disease can be produced by intranasal swabbing with active virus, and the latter has now repeatedly been demonstrated in the tonsils, the nasal mucous membrane and the nasal washings from fatal and acute cases The possibility of producing the infection by the nasal application affords an opportunity to determine the precise manner in which microorganisms may enter the body through such mucous membranes Do they first reach the blood-stream and through this the central nervous system, or does the virus ascend directly along the lymphatics that unite the nasal mucosa with the central meninges? Flexner and Clark have recently furnished an answer to this question at the Rockefeller Institute for Medical Research[1] It is known that the virus is present throughout the central nervous system in experimental poliomyelitis produced by any method of injection The investigators therefore attempted to ascertain whether or not after an intranasal introduction the virus can be demonstrated equally early in all regions of the cord The answer was definite The infective agent passes from the nasal mucous membrane to the olfactory lobes and adjacent parts of the brain before it reaches the medulla or cord This distribution, as the experimenters remark, is what we would expect were the ascent by the direct lymphatic path and not by the blood-stream Were the dissemination by the latter route, one would anticipate early localization in those parts of the cord and medulla that possess an especial affinity for the virus

Medical News

ALABAMA

New Officers—Mobile County Medical Society at Mobile, December 7 president, Dr R. H von Ezdorf, secretary, Dr W W Scales——Butler County Medical Society at Greenville, December 6 president, Dr W E Morris, Georgiana, secretary treasurer, Dr L V Stabler, Greenville——St Clare County Medical Society at Odenville, December 5 president, Dr W B Johnson, Asheville, secretary treasurer, Dr J P Hawkins, Ragland——Dallas County Medical Society at Selma president, Dr E B Ward, secretary, Dr B B Rogan, both of Selma——Houston County Medical Society at Dothan president, Dr M S Davie secretary, Dr W C Howell, both of Dothan——Perry County Medical Society at Marion president, Dr R C Hanna, secretary, Dr J B Hatchette, both of Marion——Calhoun County Medical Society at Anniston, December 3 president, Dr T J Brothers, secretary, Dr I P Levi, both of Anniston——Tuscaloosa County Medical Society at Tuscaloosa, December 4 president, Dr G H Searcy, secretary treasurer, Dr Joseph A Maxwell, both of Tuscaloosa

ILLINOIS

Sanatorium for Kane County—The Kane County Board of Supervisors, meeting in Aurora, December 11, appropriated $5 000 to purchase a site for a county tuberculosis sanatorium

Fever Closes Schools.—Public schools and churches of Chandlerville have been closed, and all public meetings have been suspended by the Board of Health because of an epidemic of scarlet fever

Dr Ferguson Not Dead—The announcement in THE JOURNAL December 14, of the death of Dr Harry Milton Ferguson of Morris, was incorrect Dr Ferguson, an esteemed member of the American Medical Association, secretary of the Grundy County Medical Society and coroner of his county, is still alive and in good health

New Officers—Vermilion County Medical Society at Danville December 9 president, Dr Frank M Mason, Rossville, secretary treasurer, Dr Solomon Jones, Danville——Adams County Medical Society at Quincy, December 9 president, Dr Ray Mercer, Loraine, secretary, Dr Elizabeth B Ball, Quincy ——Madison County Medical Society at Alton, December 6 president Dr J Mather Pfeiffenberger, Alton, secretary, Dr E W Fiegenbaum, Edwardsville The next meeting will be held at Granite City, a joint session with the Madison County Press Club

INDIANA

State Hospital Needs —Dr C E Laughlin, superintendent of the Southern Indiana Insane Hospital, Evansville, has informed the legislative committee that he will ask for appropriations of nearly $135,000 for the institution at the coming session of the legislature Of this amount $91,000 is required for two cottages where violent and untidy patients may be kept

Tuberculosis in Indiana.—November statistics of the State Board of Health show that out of 2,864 deaths during that month 233 were due to pulmonary tuberculosis ——Negotiations are being carried on by the Fort Wayne Antituberculosis Association for the purchase of a tract of land of three or four acres on which to establish a tent colony for consumptives Dr E. A Crull is in charge of the enterprise

MARYLAND

Personal —Dr George W Todd, Salisbury, has been appointed superintendent of the State Institution for the Care of Incurable Tuberculosis ——Dr J C Holdsworth, Eckhart Mines health officer of Allegany County, who has been ill with small pox, has recovered

Sanatorium Site Purchased by State —The Pine Bluff Sanatorium near Salisbury, on the Wicomico river, has been purchased as a state institution for the care of incurable tuberculosis at a cost of $15,000 The property is twenty eight acres in extent, covered with a dense growth of pine trees

Baltimore

Personal —Capt J Harry Ulrich has been commissioned chief surgeon of the Fourth Infantry, N G Md, vice Capt William Guy Townsend who has accepted a position in the U S Marine Corps ——Dr John C Stansbury has been appointed assistant surgeon, M C, N G Md ——Dr B Merrill Hopkinson gave a song recital at Lakewood N J, December 14 before the County Club ——Drs Howard A Kelly and John M T Finney addressed the congregation of Madison Avenue Methodist Episcopal Church December 15, in advocacy of the uplift of social conditions in the city Dr Kelly called the church people sharply to task for their indifference in dealing with the social evil and the saloon question

MASSACHUSETTS

Richardson's Estate —The inventory of the estate of the late Dr Maurice H Richardson shows that his personal property was valued at $218 831 and his real estate at $23,770, making a total of $242 601

To Provide Dental Nurses for School Children —The Allied Dental Societies of Greater Boston have taken action in support of a bill to be introduced in the next legislature providing for the licensing and registration of dental nurses who shall be able to help the dentists in their efforts to prevent the decay of teeth, especially among school children

MISSOURI

Personal.—Dr J A Adcock, Warrensburg, has been appointed secretary of the State Board of Health ——Drs J A Wall and J V S Esposito have resigned as members of the resident staff of the St Louis City Hospital

Ambulances to be Used for Poor —The St Louis City Hospital Board has voted to give a three months trial to the scheme of sending ambulances for sick people reported to the hospitals by organized charities At present the ambulances are used only to answer dispensary calls from the police

New Officers —St Joseph Buchanan Andrew County Medical Society at St Joseph, December 4 president, Dr A L Gray, secretary Dr W F Goetze, both of St Joseph ——Rolla District Medical Society at Rolla president, Dr R H Finley, Cuba secretary treasurer, Dr W H Breuer, St James ——Worth County Medical Society, organized at Grant City, November 28 president, Dr W E McKinlay, secretary, Dr J K Phipps, both of Grant City ——Pike County Medical Society at Louisiana, December 3 president, Dr C L Bankhead Paynesville, secretary, Dr F V Keeling, Elsberry ——St Louis County Medical Society at Clayton, December 11 president, Dr J H Armstrong Kirkwood, secretary treasurer, Dr Horine Miles, Webster Groves ——Cape Girardeau County Medical Society at Cape Girardeau, December 9 president, Dr F H G Wilson, secretary, Dr D H Hope, both of Cape Girardeau ——Grundy County Medical Society at Trenton, December 3 president, Dr J F Fair, secretary, Dr T E Moore, both of Trenton

St. Louis

Opposes Fee-Splitting —The St Louis Medical Society at its last meeting voted to cooperate with the American Medical Association in its endeavor to stamp out the practice of fee splitting and recommended that members found guilty be expelled from the society

New Hospitals —Plans have been completed for the Jewish Home for Chronic Invalids to be constructed on a fifty acre tract of land on the east side of Fee Fee Road, near Creve Cœur Lake Four principal buildings will be erected at a cost of $200,000 One of these will be known as the Shoenberg Memorial Building and will be used for the treatment of chronic cases of tuberculosis. A second building will be used solely for incurable patients suffering from diseases other than tuberculosis The third building will be for cases of incipient tuberculosis and the fourth, for other diseases supposed to be curable ——Orthodox Jews of St. Louis have subscribed $10,000 toward the erection of a Kosher Hospital, to cost $15,000 and probably to be erected adjacent to the Jewish Orthodox Old Home

NEW YORK

Physician Gives Site for Campus.—Dr John P Munn, New York City, president of the United States Life Insurance Company has offered the University of Rochester a lot 370 by 170 feet at the corner of Prince Street and University Avenue as a site for the Women's Campus

New Officers —Chautauqua County Medical Society at Amsterdam, December 11 president, Dr N G Richmond, Fredonia, secretary treasurer, Dr J W Morris, Amsterdam ——Watervliet Medical Society, December 5 president, Dr L B Rulison secretary treasurer, Dr Robert J O'Brien.

Hospital Notes.—A contract has been awarded for the construction of the Montgomery County Tuberculosis Hospital, Amsterdam, to cost about $16,000 ——The subscriptions of the first day of the donation for the Rochester General Hospital amounted to more than $10,000 ——An attempt is being made to raise $100,000 for the Infants' Summer Hospital, Charlotte ——Dr William McCleary, a trustee of the Amsterdam Hospital has presented the institution with a deed to property adjacent to the present hospital site

Corner-Stone Laid —The corner stone of the Syracuse University Medical College Dispensary building was laid with formal ceremonies, December 14 After the laying of the corner stone by Chancellor James R Day, the adjournment was made to the College of Medicine where addresses were made by Dr William S Thayer of Johns Hopkins Medical School, Baltimore, Mr Augustus S Downing, first assistant commissioner of education and Hon Allen C Fobes, representing the Syracuse Free Dispensary Association

State Society Prizes —The committee having in charge the Merritt H Cash and Lucien Howe Prizes of $100 each offers as suggestions the following subjects for essays

Diagnosis and treatment of syphilis of the central nervous system
The present status of serum therapy
Latest research relative to cancer
The order and sequence of vascular and cardiac disease
The function of the state in limiting the increase of imbeciles and degenerates
Surgery in functional and organic disorders of the stomach

The essays must be in the hands of the chairman of the committee, Dr Albert Vander Veer, 28 Eagle Street, Albany, not later than April 1, 1913

New York City

Aschoff to Deliver Cartwright Lectures —Prof Ludwig Aschoff of the University of Freiburg, Germany, has accepted an invitation to deliver the Cartwright lectures of the Alumni Association of the College of Physicians and Surgeons in March

New Home for Incurables —A number of business women and social workers have founded a Home for Incurables in a twelve room cottage at Bay Ridge, near the Shore Road, which was formally opened December 12 Dr Ambrose A Scouler will be in charge

Free Immunization Against Typhoid.—The Department of Health in its circular of December 18, announces the establishment of immunization against typhoid as an established prophylactic measure of proved efficiency, and offers free inoculation on application on and after January 1

Fire in Randall's Island Hospital —A fire broke out in Ward 28 of the New York City Children's Hospital on Randall's Island on the night of December 13 One hundred and twenty crippled children were removed from the building without mishap and the fire was extinguished by a bucket brigade formed largely of nurses

Babies' Welfare Association Permanent.—The Babies' Welfare Association, which is composed of numerous organizations interested in the reduction of infant mortality and which began its work on June 10 last, has become a permanent organization Mrs J Borden Harriman has been elected president and Dr Ernest J Lederle, Health Commissioner, has been made honorary president Representatives of other organizations were elected as vice presidents, among these being Joseph H Choate, Robert Fulton Cutting, Cardinal Farley, Dr Abraham Jacobi, Dr Ira S Wile, Robert W deForest and others There are seventy two organizations affiliated with the association Dr S Josephine Baker in her report, said that there had been 600 fewer deaths of babies in 1912 than in 1911 and that they had cared for 50,000 babies and only 125 had died Dr G R Pisek called attention to the fact that the city hospitals had no way of caring for convalescent babies and steps will be taken at once to provide for this need

NORTH CAROLINA

Work on Hospital Begun.—Work on the Patton Memorial Hospital, Hendersonville, has been commenced and it is expected that the building will be ready for patients by June 1

Personal.—Dr Henry J Alexander of Mecklenburg County has been elected president of the State Farmer's Union for the fourth term ——Dr W J Pitz, after four years in practice in Bristol, Colo , has located in Lenoir

Report of State Hospital.—The biennial report of Dr John McCampbell, superintendent of the State Hospital for the Insane, Morganton, shows that the recoveries, based on admissions, were 20 per cent in 1911 and 30 per cent in 1912, the average yearly death rate for the two years being 3 53 per cent The average cost per capita for the biennium was $162 03 Of the fund appropriated by the last legislature for the maintenance of the institution, $16,942 21 was turned back into the state treasury The report urges the need of an additional building to accommodate 200 patients and states that there are now ninety applicants on the waiting list

OHIO

Campaign for Good Samaritan Hospital.—An eight day campaign to raise $200,000 for the Good Samaritan Hospital, Cincinnati, opened December 3 under the auspices of an executive committee

Lane in Cincinnati —Mr W Arbuthnot Lane, London, gave a demonstration and lecture before the Cincinnati Academy of Medicine, November 25, at the City Hospital Mr Lane sailed for home November 26

Staff Appointments —At the annual meeting of the Volunteer Medical and Surgical Consulting Staff of the Ohio Soldiers and Sailors' Orphans Home, Xenia, Dr R H Grube, Xenia, was appointed dean of the staff and Dr P R Madden Xenia, secretary Drs E. S Breese, Dayton, C M Shepherd and C J Shepherd, Columbus, were elected members of the staff

Ill and Injured.—Dr O M Hendershot, East Liverpool, who has been ill for two weeks, is reported to be improving —— Dr C N Chrisman, Dayton, who was operated on in Chicago recently, has recovered and returned home ——Dr E von den Steinen, athletic director of Western Reserve University Cleveland, was operated on for appendicitis November 30 and is reported to be doing well ——Dr J M Hensley, Bellaire, is reported to be seriously ill ——Dr J M Hoskins, Marion, was accidentally shot in the shoulder while hunting, November 19 ——Dr M J Davis, Mansfield, who was operated on recently for appendicitis, has recovered and resumed practice

New Officers —Belmont County Medical Society at Bellaire, December 10 president, Dr J C Meek, secretary, Dr A C Beetham both of Bellaire ——Hancock County Medical Society at Findlay president, Dr T S Wilson, secretary, Dr Cornelia B Kennedy ——Montgomery County Medical Society at Dayton December 6 president, Dr W C Marshall, secretary, Dr C C McLean, both of Dayton ——Tuscarawas County Medical Association Dr E. D Moore, New Philadelphia, president ——Summit County Medical Society at Akron, December 3 president, Dr G M. Logan, secretary, Dr A S McCormick, both of Akron ——Athens County Medical Society at Athens, December 3 president, Dr J M. Hyde, Nelsonville, secretary treasurer, Dr T A Copeland, Athens —— Williams County Medical Society at Bryan president, Dr J A Weitz, Montpelier, secretary treasurer, Dr D S Burns, Bryan ——Eighth Councillor District Medical Society at Marietta president, Dr H R Gever, secretary treasurer, Dr J R McDowell, both of Zanesville

PENNSYLVANIA

Aim of Red Cross Stamps —Circulars in sixteen different languages explaining the purpose of the campaign were distributed from the Red Cross Seal Booth in the post office by the Pennsylvania Society for the Prevention of Tuberculosis

Gift to University —Mrs Montgomery has presented the zoologic department of the University of Pennsylvania with the valuable collection of microscopic slides and preparations left by her husband The collection comprises upward of 3,800 mounted pieces and slides in addition to a large number of objects embedded in paraffin

Hospital Contract Halted.—The county commissioners presented, December 9, a petition asking for a rule to show cause why the construction of the new hospital for the insane at Schuylkill Haven, now under contract, should not be completed by the county officials The rule was granted and an early hearing decided on The new building was to have been completed by July of last year

State Charities Make Large Demands —The State Board of Charities convened, December 11, and meetings will be held until January 1 Appropriations requested by the various state charitable institutions amounted to $4,000,000 more than was asked by the same institutions last year Last year $19,000,000 was asked and $16,000,000 was granted, and it is thought that the legislature will grant no larger sum this year Committees appointed by the board have been investigating the institutions who have asked state aid, and the report of these will have great weight in determining which institutions shall gain or suffer in the board's recommendation to the legislature

Contagious Diseases —Chester High School and Lincoln School buildings, Chester, were again closed for fumigation, December 10, because of diphtheria, while the Starr and Garside Schools were closed December 9, because of scarlet fever ——The community of Norwood, Delaware County, has such an epidemic of measles that public schools and all places of amusement have been ordered closed for twelve days The entire district seems affected There are thirty five cases in Prospect Park, adjoining Norwood ——On December 11, the Board of Control closed the Schuylkill Avenue School building, Reading, because seven cases of typhoid have developed among the pupils ——The typhoid epidemic at Troy, Bradford County, is under control, the emergency hospital is to be closed and patients under quarantine released In all there were 225 cases of the fever and 16 deaths ——The Elizabethville epidemic is also abating, the present record showing 21 persons quarantined, 5 deaths and 5 recoveries

Philadelphia

Dinner to Jefferson Hospital Staff —Mr Daniel Baugh, a member of the board of trustees, gave a dinner, December 12, to the staff of the Jefferson Hospital Dr Hobart A Hare was the toastmaster and impromptu speeches were made by Drs J Chalmers DaCosta, Thomas McCrae, W M Late Coplin and others

Forced to Hold Daily Clinics.—The new Gray's Ferry Dispensary for the treatment of tuberculosis, recently opened in the southwestern section of the city has had such great demands made on it that beginning, December 9, the dispensary will be open daily from 10 12, instead of three times a week The staff of examining physicians has been increased from one to four and additional visiting nurse has been added

Formal Opening of Phipps Institute Postponed.—At the meeting of the board of trustees of the University of Pennsylvania, it was announced the Phipps Institute's new building at Seventh and Lombard Streets, will not be formally opened until next June, although the building will be partly occupied in January and will be entirely open in February, because Henry Phipps, who gave the building to the university will not be able to be present on February 22, the time first planned for the opening

GENERAL

Surgeon General Reappointed—It is announced from Washington that the president has decided to reappoint Brigadier General George H Torney as surgeon general of the Army General Torney does not reach the age for retirement until 1914

New Officers—Seaboard Medical Association at Newbern, December 3 5 president, Dr J F Rawls, Suffolk, Va , secretary, Dr C P Jones, Newport News, Va ——Nu sigma Nu Fraternity at Baltimore, November 29 and 30 president, Dr H W Stiles, Syracuse, N Y , secretary treasurer, Dr E E Irons Chicago

Hookworm Conference—The annual session of the Southern Conference for the Eradication of Hookworm, at Little Rock, Ark closed December 18 19, with the election of Dr Olin West, Nashville, Tenn , as president, Drs A G Fort, Atlanta, Ga and La Bruce Ward, Charleston, S C , as vice presidents, and Dr S D Porter, New Orleans, as secretary treasurer

Personal—Dr Randolph W McDowell, U S Navy, sustained a concussion of the brain and fracture of the collar bone and two ribs in a collision between an automobile and a street car in Philadelphia, November 28 ——Surgeons S S Rodman and I S K Reeves and Drs D C Cather and W E Eaton, U S Navy, were given medals by the government of Santo Domingo for their services in attending the wounded at the battle of Azua

Meeting of Southern Surgeons and Gynecologists—At the annual meeting of the Southern Surgical and Gynecological Association held in Newport News, Va , December 17 19, Atlanta, Ga., was selected as the next place of meeting and the following officers were elected president, Dr John Young Brown St Louis, vice presidents Drs Ap Morgan Vance, Louisville, and Lomax Gwathmey, Norfolk, Va , secretary, Dr W D Haggard, Nashville, Tenn , and treasurer, Dr Le Grand Guerry, Columbia, S C

For Travelers' Health.—At the meeting of the Northwestern Sanitation Conference in St Paul, December 5, a representation of all the northwestern railroads, resolutions were adopted calling for the introduction of bills in the coming session of the legislature of the various states, providing for the abolition of the common drinking cup and roller towel, the fumigation of sleeping cars every two months, the sweeping of cars with formaldehyd and airing and cleansing of all berth clothing after each trip, and the reporting of all illness on any train by the conductor to a physician at the next stop made

LONDON LETTER

(From Our Regular Correspondent)

London, Dec 7, 1912

Medical Education

Medical education is a subject of perennial discussion and many schemes of reform are brought forward which never mature A single portal by a state examination, such as exists in many Continental countries, has long been advocated but seems no nearer fulfilment It offers the obvious advantage of a uniform standard which can be adjusted to any level of knowledge thought desirable At present, about fifteen universities grant degrees in medicine and in addition there are several colleges which grant licenses to practice Thus there are more than twenty avenues to qualification The General Medical Council appoints inspectors to visit the various examinations and see that a proper standard is maintained, but this is a much less efficient method than a uniform single examination It is well known that the examinations of different bodies vary considerably in standard Moreover, the fact that some competition exists between the different licensing bodies has a tendency to lower the standard The General Medical Council also supervises medical education and here, by its regulations, ensures a certain uniformity Thus a five year course of study and attendance on lectures in the various branches of medicine and the ancillary sciences, as well as the passing of various examinations, is rendered obligatory This five year course is an extension of the course which existed some years ago and amounted to only four years Now the growth of science, especially of physiology and biochemistry, has been so great in recent years that five years is not regarded as sufficient, but the increased expense stands in the way of the adoption of a six year course A way out of the difficulty, advocated by some reformers, is to exclude the preliminary sciences, such as chemistry and physics, from the med curriculum and insist on a certificate of knowledge of t before entering on it Thus the whole of the five years can be devoted to medical study This is the method adopted in France

The Increasing Sale of Nostrums

In spite of the campaign against secret remedies their sale appears to be increasing According to statistics issued by the Board of Customs and Excise the revenue from medicine stamp duty for the year ending March 31, 1912, was $1,600,000, an increase of $10,000 on the preceding year On this basis the amount spent on secret remedies in Great Britain can be approximately calculated All shilling (24 cent) packages must bear a 3 cent stamp The revenue would therefore account for over 52,000,000 shilling packages, which would be sold for $12,500,000 This estimate is subject to the correction that some of the nostrums are of higher value and bear a higher revenue duty, but this correction would not make a substantial difference The number of licenses issued during the year to venders of nostrums was 43,131, a slight increase on the preceding year

PARIS LETTER

(From Our Regular Correspondent)

Paris, Dec 6, 1912

The Choice of Experts

The right of the general practitioner to give medicolegal evidence is seriously menaced by the vote which was recently taken at the Congrès de médecine légale approving the restriction of the privilege of making reports on industrial accidents to medicolegal experts alone. On the other hand, a recent court decision declared a report null because it had not been made by the physician who, although appointed by a magistrate and fully competent otherwise, was not in the list of experts named by the court of appeal Owing to this condition of things the Syndicat médical de Paris discussed the question at its last general meeting, at which the following conclusions were reached In view of the necessity in practicing medicine for the physician to have a working knowledge of legal medicine (1) thorough medicolegal instruction should be given again in all the Facultés de médecine with examinations, (2) the diploma of *médecin légiste*, since it is useless and prejudicial to holders of a professional diploma, ought not to be given On the other hand, as moral and scientific guarantees are required of criminal experts and as the selection of these can be made only by their peers, who alone are competent to select them, the *syndicat* voted that the courts of appeal should consult professional and scientific men before drawing up the list of authorized criminal experts Since civil expert reports, especially those of industrial accidents, require no information which it is not within the powers of general practitioners to furnish, the magistrate should not be forced legally to select medicolegal experts from the list drawn up by the court of appeal.

The Physicians' Home

Some years ago a number of physicians endeavored to establish a house of refuge for aged and destitute physicians By donations they were enabled to purchase the little property of Brézolles, a few miles from Dreux (Eure et Loire) Thus three years ago the Maison du médecin was established to receive unfortunate physicians who through ill luck, sickness or improvidence found themselves in distress at the end of their career Besides the kitchen, dining room and sitting room, the house at Brézolles has six sleeping rooms The most unfortunate are kept free of charge, but those who are able pay rent The house is opened to all French physicians, civil, military, naval or from the colonies and their wives or widows A special commission decides which applicants shall be admitted, giving preference to those who are oldest and who have suffered the greatest misfortune For two years the Maison du médecin has taken care of ten pensioners, but as there are forty on the waiting list, and as they cannot be taken care of owing to lack of room, the association is trying to enlarge the place or to buy another For this purpose they are conducting a charity sale on the premises of the Faculté de médecine and have already raised the sum of 35,000 francs ($7, [illegible]

[illegible] lezenne to [illegible] my of Medicine

[illegible] le médecine by [illegible] Delezenne [illegible] ysic [illegible] when admitted to the hospital and the other from tonsillitis Calomel had been administered to both of these babies for a number of weeks *before* the two little patients were admitted to Dr Abt's service In both cases the calomel was immediately stopped as soon as the babies were admitted to the hospital and improvement at once followed In the case of pyelitis, Dr Abt says, "An infant 6 months of age who had received a cathartic drug in some form every day since birth was recently brought to the writer For the first few weeks of life calomel was given every other day Later on calomel was being administered in doses varying from 3/10 to 2 grains daily for two weeks All cathartics were withdrawn" In the other case Dr Abt says, "The writer recently saw a little patient of 4 years who was taken ill about ten days previously with a tonsillar affection The physician in charge began treatment with 1 grain of calomel per day, and continued the administration of this remedy until the writer saw the patient on the tenth day It was only necessary to stop the calomel and treat the mucous membrane with astringent remedies to effect a cure in a few days"

The point of my remarks was that both of the babies in question had been given large doses of cathartics before they were admitted to the hospital, and that the withdrawal of the calomel and the administration of proper food were at once followed by improvement The stenographer who reported my discussion evidently misunderstood me No "experiments" were carried on with "normal babies" The report of my remarks as given in last week's Journal is entirely incorrect and misleading

Julius H Hess, Chicago

Queries and Minor Notes

Anonymous Communications will not be noticed Every letter must contain the writer's name and address but these will be omitted on request

TREATMENT OF COMEDONES

To the Editor —A trifle which is yet of much importance for the general practitioner is the presence of blackheads on the face especially in the alae nasi regions. What is a good treatment for their eradication without any subsequent cosmetic defect? How satisfy the patients?

J S L.

Answer.—The skin should be rubbed with a tincture of green soap and washed vigorously with warm water, care being taken not to produce too great an amount of irritation The blackheads, or comedones, can be removed by pressure by clean thumb nails or by the use of a comedo extractor At the same time such internal treatment should be given as will promote a healthy condition of the skin Special attention should be given to the condition of the digestive tract and to the prevention of constipation The subject is thoroughly discussed in works on skin diseases under the head of acne

USE OF TUBERCULIN—THE WASSERMANN REACTION IN NON SYPHILITICS

To the Editor —1 What is your opinion in regard to the reliability of tuberculin as a test for tuberculosis? Would you recommend its use?

2 Is it possible to get a positive Wassermann reaction in a non syphilitic patient? If so what are the conditions of the patient?

J M Blum M D Edgemont S Dak.

Answer.—1 See The Journal, Nov 30, 1912, p 1992

2 The Wassermann reaction is sometimes positive in patients with other diseases principally scarlet fever, frambesia and cancer These conditions, however, can usually be eliminated by the history and circumstances of the patient Aside from such cases, a positive Wassermann reaction is an evidence of uncured syphilis

BINET-SIMON TEST FOR CHILDREN'S MENTAL CAPACITY

12 *Purpura in the Course of Chronic Pulmonary Tuberculosis J M Cruice Philadelphia.

2 **Effects of Aconite on the Pulse-Rate** —During the past year the authors have tested the drug in many cases as regards the effects on the pulse rate, always using medicinal doses, and this paper gives the results of their work They used the ordinary B P tincture The pulse rate was usually taken for hours before and for hours after the administration, and in many cases the blood pressure was also measured, but no effect on the circulation was detected Often considerable fluctuations were seen, but it was found that these were mere coincidences and were just as apt to occur without the aconite After finding no effects from the administration of these tinctures they secured a quantity of B P tincture "which had been tested by physiologically and by assay in the laboratory, and which was guaranteed to be of B P strength" Most of the experiments were done with this tincture, and were still negative Crystalline aconitin, found by experiments on animals to be of full activity in solution corresponding in strength to the B P tincture, still gave negative results It appears from these findings that the tincture of aconite on the market is usually inert

3 **Lupus Erythematosus and Raynaud's Disease.**—Hartzell believes that the relationship which exists between these two maladies may be best explained by supposing both at times to be due to a common cause, most probably some toxin circulating in the blood, which acts primarily on the vessel walls producing vasomotor and inflammatory changes in the skin and subcutaneous tissues Cases of the kind here considered seem to go far in support of the view that erythematous lupus should be regarded as a toxic erythema

5 **Bence Jones Proteinuria** —The authors have observed four cases in fifteen months It would seem that this type of pro-

teinuria is probably more common than the literature would lead one to suppose Of these cases, two were clinically multiple myeloma, and a third was probably of the same type, although they have no objective proof The fourth case was one of metastatic carcinoma from the breast It is especially interesting to note that the detection of the last three cases followed definitely the interest aroused among local physicians by the presence of the first case, which led them to test the urine of their patients more carefully The recognition of the Bence Jones body in the urine in each instance antedated any suspicion of the true nature of the malady, with the exception of the last case, which was clearly associated with carcinomatous metastases That this type of proteinuria may be present for some time before any clinical evidence of myelomatosis appears is shown by the first three cases noted

6 **Gonococcus Complement-Fixation Test.**—The authors summarize their findings as follows A positive reaction denotes the presence or recent activity in the body of a focus of living gonococci A negative reaction does not exclude gonococcus infection but, for the reasons stated, should be accorded considerable importance A strong positive reaction is not to be expected earlier than about the fourth week, and then only in very acute cases with some complication A positive reaction is not obtained if the disease is limited to the anterior urethra A positive reaction does not entirely disappear until seven or eight weeks after cure In other words, if a strong positive reaction is obtained seven or eight weeks after apparent clinical cure, the patient should be looked on as still harboring gonococci In chronic cases, isolation of the gonococcus in culture is the only absolute, bacteriologic proof of gonococcus infection The technic of a complement fixation test is simpler than that of isolation of the gonococcus in culture and the possibilities of error are less In cases regarded clinically as postgonorrheal, a positive reaction is obtained in 31 4 per cent In sixty two cases of chronic prostatitis giving a history of gonococcus infection within three years, a positive reaction was obtained in 54 8 per cent In 165 patients looked on as clinically cured for at least three months, a positive reaction was obtained in 13 2 per cent In women, a positive reaction is probably not obtained unless there is at least some involvement of the cervix. On account of the unreliability of the bacteriologic diagnosis of gonococcus infection in women, the complement fixation test should prove of special usefulness in gynecologic conditions

9 **Softening of Spinal Cord After Salvarsan.**—A man who had been infected with syphilis three years before presented the first symptoms of a fatal softening of the cord fifty six hours after an injection of salvarsan

12 **Purpura in Tuberculosis**—Eight cases of purpura seen by Cruice occurred in the terminal stage of chronic pulmonary tuberculosis The first case was an undoubted case of purpura hemorrhagica, and occurred only five days before death A second case, although there was hematuria and at one time bloody stools accompanying a diarrhea, was simple purpura, the hematuria being accounted for by tuberculosis of the kidney, ureter and bladder Four cases were instances of simple or cachectic purpura One case, in which the thrombosis of the internal saphenous vein was the exciting cause, was what Osler calls a mechanical purpura, being caused by a venous stasis The last case might be called either a simple purpura complicating the tuberculosis or a toxic purpura complicating the intense jaundice Whether, however, a simple or a toxic purpura it was a purpura occurring at the termination of chronic pulmonary tuberculosis complicated by a most unusual form of caseous tuberculosis of the liver

13 **Chemistry of Blood Serum**—The most striking feature observed by Epstein in this study is the extensive variation of the blood serum in relation to its proteins It was found that in certain diseases the globulin fraction is markedly increased, whereas the total protein of the serum may be normal, or may fall far below normal in amount The diseases in which an increase in the globulins takes place are grouped as follows (1) cardiac diseases associated with decompensation and serous effusions, (2) pulmonary or respiratory affections of inflammatory or non inflammatory origin (pneumonia, emphysema, polycythemia), (3) diabetes mellitus, and (4) parenchymatous nephritis In the serum of chronic parenchymatous nephritis the increase in the globulin content was most pronounced and constituted nearly all the protein, or as much as 95 per cent The globulin content of serum was normal or diminished in the following diseases (1) simple achylia gastrica (short duration), (2) tuberculosis, (3) diabetes insipidus, and (4) chronic interstitial nephritis Other ingredients of the sera analyzed showed variations which could not be definitely classified, but in a general way it appears on careful analysis that an accumulation of water and salt occurs in diseases in which the globulin fraction of the blood serum is increased

14 **Effects of Stimulation of Two Vagus Nerves**—It is concluded by Cohn from results obtained by experiments that stimulation of the right vagus nerve in the dog usually causes arrest of all the chambers of the heart, stimulation of the left vagus nerve exerts a moderate negative chronotropic effect on the auricles, stimulation of the left vagus nerve has a profound effect on the conduction of impulses over the auriculoventricular system The degree of effect exercised on the auriculoventricular system by stimulation of the left vagus nerve varies In some dogs conduction is depressed to an extent which causes only a delay in the conduction of impulses from auricles to ventricles (P R time), in other dogs the conduction is depressed to a degree which results in incomplete heart block, while in still other dogs conduction is so depressed that although the auricles continue to contract, no impulses pass from them to the ventricles When stimulation of either the right or left vagus nerve causes asystole of nomotopic ventricular contractions, ectopic ventricular contractions may occur The time which elapses before ectopic ventricular contractions occur depends on the irritability of the ventricular muscle and this may vary in different dogs Stimulation of the left vagus nerve may rarely cause sino auricular block Possibly stimulation of the right nerve may also produce this effect There is consequently usually a great qualitative difference in the action of the two vagus nerves on the heart of the dog

15 **Changes in Blood After Splenectomy**—The results of a study of the changes in the blood after splenectomy and of the effect of the administration of hemolytic serum lead the authors to the following tentative conclusions (1) The failure of a hemolytic serum to cause jaundice is due in some way to the [illegible] uch frequently follows splenectomy Animals, [illegible] or not [illegible] ave a low blood count [illegible] ly develop jaundice [illegible] the other ha [illegible] serum r [illegible] ll m

jaundice (2) The difficulty of producing hemoglobinemia and jaundice in animals splenectomized one month or more, is due, as shown by blood count, to the use of hypotonic salt solution test, and by the search for the presence of hemoglobin in the serum and urine to an increase in the resistance of the red cells The results of detailed serologic tests on this point will be presented later (3) It is possible that spontaneous jaundice occurring at long periods after splenectomy is an accompaniment of the complete regeneration of the blood The study of the blood in animals splenectomized for long periods, seven to ten months, indicates that spontaneous jaundice occurs only when the animal has recovered from the initial period of anemia and has a high cell count and high hemoglobin content (4) As to the mechanism responsible for the anemia following splenectomy and for the increased resistance of the red cells, they offer no explanation

16 **Increased Resistance of Red Cells After Splenectomy**—The authors found that the erythrocytes of splenectomized dogs show increased resistance to the action of hypotonic salt solutions and to specific hemolytic immune serum The degree of resistance appears to increase with the length of time that has elapsed after splenectomy This increased resistance of the erythrocytes is not due to an increased antihemolytic power of the animal's serum or to a diminished complementary value of the serum, but is a property depending on the erythrocytes themselves Non splenectomized animals receiving a single injection of specific hemolytic immune serum and developing a temporary anemia show likewise on recovery an increased resistance of the corpuscles without the presence of antihemolysin in demonstrable amount As anemia of varying grade is a characteristic result of splenectomy, it would appear that the increased resistance of the corpuscles is a concomitant of the regeneration of the red cells following such anemia and is thus analogous to the increased resistance of such cells not infrequently observed in various forms of experimental anemia There is no evidence to indicate that the anemia after splenectomy is due to the presence of hemolytic bodies, or that the increased resistance of the cells is due to antihemolytic bodies, accumulating in the serum as the result of the ablation of the spleen It is evident, therefore, that the spleen in some way controls or regulates blood destruction (and regeneration?), and in the hope of throwing light on the subject, an investigation of the bone marrow and lymph nodes of splenectomized dogs is now under way

17 **Increase in Number of Endothelial Cells of Lymph Nodes After Splenectomy**—In a large proportion of dogs that had been splenectomized for periods of two weeks or more, the authors found a great increase in the number of endothelial cells of the lymph nodes In most splenectomized dogs that succumbed to an injection of hemolytic immune serum within forty eight hours, the sinuses of the lymph nodes contained large numbers of endothelial cells, phagocytic for red cells This was not seen in normal dogs receiving hemolytic serum Likewise a similar power of phagocytosis was seen frequently in the stellate cells of the capillaries of the liver Both in the lymph nodes and the liver these cells appeared to be formed *in situ* The authors found no evidence that they have been transported to these organs They suggest the possibility of the lymph nodes assuming some of the function of the spleen

19 **Pathology of Primary Splenomegaly**—Mandlebaum maintains that primary splenomegaly of the Gaucher type is a distinct disease related in all probability to the blood diseases It begins usually at an early age frequently affects several members of a family and runs a chronic course The clinical manifestations are pronounced hypertrophy of the spleen subsequent enlargement of the liver, absence of palpable lymph nodes, absence of jaundice and ascites, absence of characteristic blood changes, discoloration or pigmentation of the skin and a tendency to epistaxis or other hemorrhages The lesions are found in the spleen, lymph nodes, bone marrow and liver These organs show the presence of iron coating pigment, and large multinuclear cells with a characteristic cytoplasm In the early cases peculiar large phagocytic cells arising from atypical large lymphocytes are found in the follicles (keim centra) of the hemapoietic system After leaving the follicles these cells possess phagocytic qualities for a certain period As a result of the phagocytosis the cells enlarge, the nature of the cytoplasm changes, and the cells acquire a characteristic vacuolated and wrinkled appearance The cells are carried from the spleen through the portal system of the liver, where they are destroyed The irritation produced by this destructive process gives rise to an increase in the intralobular connective tissue The disease is eminently a chronic one, without any of the manifestations of malignancy, and always terminating as the result of some intercurrent affection The etiology is unknown, although a family predisposition to some toxic agent which causes an irritability of the follicles in the hemapoietic system probably exists The possibility of some protozoan infection as an etiologic factor must not be overlooked.

22 **Insect Transmission of Virus of Poliomyelitis**—It is claimed by Howard and Clark that the domestic fly (*Musca domestica*) can carry the virus of poliomyelitis in an active state for several days on the surface of the body and for several hours within the gastro intestinal tract Mosquitoes (*Culex pipiens, C sollicitans* and *C cantator*), in their experiments, have not taken up and maintained in a living state the virus from the spinal cord of monkeys Lice (*Pediculus capitis* and *P vestimenti*) have not taken the virus out of the blood of monkeys or maintained it in a living state The bedbug (*Cimex lectularius*) has taken the virus with the blood from infected monkeys and maintained it in a living state within the body for a period of seven days

3 Case of Rheumatoid Arthritis in Child Six Years of Age. W R Jordan

2 **Cutaneous Reaction to Tuberculin in Childhood**—To determine the value of the cutaneous reaction in the diagnosis of tuberculosis in children Lapage collected and analyzed the results of the tests in 1 000 children These have been chiefly children showing indefinite signs which may point to tuberculosis All the cases tested have been carefully examined clinically by the ordinary methods of physical examination The number of children reacting to the test increased steadily with advancing age, although probably the increase of infection is not so rapid after the tenth year In the less suspicious cases comprising the last 483 cases, a smaller percentage of children reacted at each age period The reaction occurs with a steadily

increasing frequency as the clinical examination progresses from negative to definite The older the child is, the higher is the percentage of clinically doubtful cases giving a reaction There is greater difficulty in diagnosing tuberculous infection after the age of 2 years by clinical examination This is explained by the fact that in older cases tuberculous infection is very common and is not the cause of the illness under consideration On the other hand, in infants up to the age of 2 years, an infection has such marked results and is so often fatal that the clinical diagnosis is more easily made Thus we see that as indicating a tuberculous illness the test is likely to be of greater value in young than in older children

7 **Cirrhosis of Liver**—The early symptoms of cirrhosis, Duckworth says, demand treatment for the gastric catarrh and intestinal sub inflammatory conditions Tartrate of sodium in effervescence is useful for this, with a few minims of dilute hydrocyanic acid in each dose, given every six hours Milk and arrowroot, or yolk of egg and milk, is an appropriate diet Whey, or curds and whey, and Koumis are useful A mustard cataplasm to the epigastrium is helpful, if there is a tendency to esophagismus or vomiting Bromid of ammonium relieves the irritability of the pharynx When the digestive powers return, the best treatment for the liver consists in full doses of ammonium chlorid and liquid extract of taraxacum, sweetened with liquid extract of liquorice, this should be maintained for some weeks If the digestive powers are weak, sodium bicarbonate with gentian, rhubarb, tincture of capsicum and some nux vomica will prove of advantage All strong liquors are forbidden, and all precautions taken to ensure this The patient should be duly informed as to the nature of his ailment, and made to understand the risks of continuance in his vicious acquired habits Inunction with biniodid of mercury ointment may be carried out from time to time over the hepatic region

16 **Inunction Treatment of Measles**—As soon as the child is received into the special ward assigned to measles, a hot bath is given Then follows a thorough application of eucalyptus oil to the whole of the body, with the exception of the hands and the part of the face round about the nose, mouth and eyes The mouth is irrigated twice daily with weak alum lotion, and glycerin and borax is applied to the interior of the mouth and to the gums The throat (tonsils and fauces) is treated with carbolic oil (1 10) morning and evening Every day for the following four days the child s blanket bathed morning and evening, and again rubbed all over with eucalyptus oil, the throat and mouth having the same treatment as on admission In most of the cases, it was found by Connolly that the gums were very red and more or less swollen, and often quite definite ulceration was present on the inner side of the cheeks and lips, much larger and whiter than Koplik's spots Further it was believed that by attacking the mouth and throat he was striking at one of the chief strongholds of the virus Connolly is of the opinion that the moist spray and particles, coughed out by the patient, are highly infectious to a susceptible person In those cases in which bronchopneumonia is already established, the statement holds true to a greater degree

As regards the thorough rubbing in of the eucalyptus oil, some local effect would, doubtless, be produced, but the main idea was to get the vapor inhaled into the air passages If the virus were dwelling in the skin or the subcutaneous tissues, it seems reasonable to suppose, too, that direct conflict would take place between the eucalyptus absorbed and such virus as might be present The face area was omitted, because of the irritation caused to the eyes by the vapor, and it was not thought necessary to apply the oil to the hands The total number of patients so treated was 160, of these complications were present in 110, equal to a percentage of 68 75 per cent In fifty cases complications were absent throughout, a percentage of 31 25 per cent Forty of the children, 25 per cent, had more than one complication Complications were already present on admission in ninety nine cases 61 9 per cent, while in eleven cases (6 9 per cent) complications developed in the course of the disease Bronchopneumonia was present on admission in nineteen cases, or 11 9 per cent., and in two other instances it developed later Inflammation of the eyes, including acute and chronic conjunctivitis and trachoma, was in evidence twenty nine times (18 1 per cent) Another frequent complication was stomatitis, present in twenty one cases (13 1 per cent) Gastro enteritis, most often severe, occurred in twelve children (7.5 per cent), while a simple gastric catarrh was noticed in two cases Another fairly frequent and troublesome complaint (always when found, present on admission) was vulvitis in little girls, being observed in twelve cases (7 5 per cent) A similar percentage of the children had bronchitis (7 5 per cent) Otitis media complicated the measles in six cases (3 75 per cent), in four of these it was present on admission In eleven cases (6 19 per cent), acute laryngitis was a serious complication Inflamed tonsils were observed seven times (4 4 per cent), and skin diseases, such as ringworm, eczema and intertrigo, were present in six cases (3 75 per cent) Whooping cough developed in two children (1 25 per cent) early in the disease, and meningitis was present in the same number on admission In one doubtful case of measles meningitis developed some days after admission The remaining complications were tetany (one), tubercular disease (two), both on admission and one child had an axillary abscess due to a septic focus in the right upper arm

The total number of deaths was eight, giving a case mortality of 5 per cent Comparing this result with the case mortality prevailing before the introduction of the inunction method and its accessories, Connolly found that there were 100 cases of measles at the Manchester Union Hospital during the period extending from April 1910, to the early part of May, 1911 The total number of deaths in this period was eleven, a case mortality, of course, of 11 per cent The first death in Connolly s series coincided with the one hundred and thirty third case Seven were due to gastro enteritis, which disease was present on admission One child had only slight gastro enteritis, and had a doubtful history of measles just previous to admission, meningitis supervened later Among the seven just mentioned, one was dying from tuberculous cachexia

t

far apart and there are thus three loose pieces with possibly additional sequesters He describes three cases in which clinically normal conditions were restored in a remarkably short time by the technic described with twenty illustrations It is not applicable for a compound fracture, but only when there is absolute asepsis of the tissues to be operated on After the accident the leg is cleansed, disinfected and temporarily immobilized in a wire splint until any excoriation of the skin has healed In about a week he paints the region with iodin and operates with tricot gloves drawn over rubber gloves to protect them He obtains access to the fracture from the front by a U incision and saws through the patella or through the anterior tuberosity of the tibia The flap of bone and soft tissue thus formed is turned back the knee is flexed still more, and after cleansing the joint and region of clots, etc, the condyles are reduced and held in place with screws and the epiphysis is then reduced, the leg extended straight, and a metal plate is screwed to hold the parts in good position or a wire is wound around them Two patients were women of about 42 the other a man of 32 The conditions were determined by radiography two or three days after the trauma The eighth day after the operation the leg was left free in bed, the patient was allowed to get up the thirty fifth day, and by the forty fifth day in one case and the seventy fifth in the other, was using the leg normally without any support The radiographs show the unusually complex nature of the fractures, and Alglave declares that no other technic could possibly have given such functional results in such a short time

23 **Chronic Nephritis**—Widal emphasizes that the progress of science has made the examination of a patient with nephritis now mainly a problem in physiology The important point is to determine the functional capacity of the kidneys It is no longer enough to say that the patient has acute or chronic nephritis of interstitial or parenchymatous origin, the diagnosis now must be completed with the specification as to whether the disease has a single or a multiple syndrome, that is whether there is retention of chlorids or of nitrogen and whether there is abnormally high blood pressure isolated or associated Modern science enables the symptoms from each of the above to be sorted out and the treatment applied accordingly

33 *By Effects of Hormonal (Ueber Hormonalwirkung) A Schönstadt

26 **Tuberculin Treatment of Fever in Pulmonary Tuberculosis**—Samson reports convincing evidence as to the efficiency of minute doses of tuberculin in arresting the fever and thus improving the general condition and affording other measures a chance to work He gives the tuberculin for this purpose in extremely small doses, the aim being not to induce tolerance and lead up to large doses but merely to influence the organism in such a way that it can get the upper hand of the fever By thus limiting the disease to its focus, the patient recovers if a cure is possible, the nearer to the hectic type, the less promising the outlook He thinks the special tuberculin to be used is of comparatively less importance The temperature curve in eight clinical cases is shown demonstrating the effect on the fever which had proved rebellious to all other measures In the first case he commenced with 0 0001 mg "old" tuberculin and the temperature began to go down when 0 0015 mg was reached His closing dose was 10 mg with a four months' course The patient was a boy of 14 with a large cavity in the left lung and temperature of 38 1 C (over 100 F) after three months of general sanatorium treatment He is now in good condition, two years later

29 **Etiology of Vasomotor-Trophic Disturbances**—In the case described by Zweig the syndrome was made up of three different sets of symptoms, from abnormal conditions in the circulation, in the thyroid and in the psyche In this, as in Roth's similar case, there was evidently a constitutional overexcitability of the sympathetic nerve system, and of its vasomotor elements in particular, the thyroid syndrome was evidently secondary to this In exophthalmic goiter, on the other hand, the thyroid element is the primary factor, the rest of the syndrome being consecutive to the abnormal thyroid functioning The psychic disturbances in Zweig's case persisted unmodified after the other symptoms had subsided confirming its independence of the thyroid and cardiovascular functioning The somatic symptoms and the abnormal psychic reactions were probably all traceable to a third element, probably the product of some disturbance in the internal secretions acting on a constitutionally predisposed brain and nervous system The main symptoms were acute hallucinations, recurring urticaria—suggesting an angioneurotic purpura—sudden enlargement of the thyroid tremor, exophthalmos, rapid pulse, etc, but no albuminuria and no symptoms on the part of the heart at any time The patient was an unmarried woman of 52

31 **Sarcoma in Muscle**—Landois states that in the last eleven years at the Breslau surgical clinic twenty cases of sarcoma in the soft parts have been encountered, and in nine of these the sarcoma was in the muscles, on the arm in two men of 38 and 44, on the leg in four men between 19 and 36, on the trunk in two women, 15 and 38, and on the head in a girl of 15 The tumor was successfully removed in only five of the cases (leg and trunk), but three in this group already have a recurrence, so that only two of the patients were cured by the operation, the interval since being one and two years The unfavorable prognosis in these muscle sarcomas should compel early and exceptionally radical removal of the growth

33 **By Effects of Hormonal**—Schönstadt reports three cases of appendicitic peritonitis in which he gave hormonal, and he deplores the fact that this medicinal article was placed in the hands of the general practitioner without a warning that it contains an element liable to induce a serious drop in the blood pressure He was appalled at its by effects in one case A man of 68 with good and strong pulse at 120 was given an intravenous injection of 0.2 c c of hormonal according to directions Two minutes afterward there was general tremor, then convulsive twitchings, collapse, and death the twentieth minute In another case a robust man of 32 was given an injection of 0 2 c c. without the slightest effect being apparent. A fresh supply was obtained directly from the manufacturers and a second injection given the next morning, but no effect on the intestine or heart followed There was likewise no sign of a reaction to the hormonal in his third case, the peritonitis progressing to a fatal termination about the third day apparently uninfluenced by the hormonal, although there was no paralysis of the intestines in either of these latter cases

Deutsche medizinische Wochenschrift, Berlin

November 21 XXXVIII, No 47, pp 2201 2248

34 Antisepsis and Asepsis F Pels Leusden
35 *Traumatic Exophthalmic Goiter (Zum Kapitel des traumatischen Morbus Basedow) F Dyrenfurth
36 Formation of Vagina Out of Small Intestine Two Cases (Künstliche Scheidenbildung aus dem Dünndarm) M Henkel
37 Technic for Concentrated Mercurial Treatment of Syphilis. (Zur Technik der Anwendung hochkonzentrierter Quecksilbermischungen in der Syphilisbehandlung) K Zieler
38 *Toxicity of Urine and Measles (Harntoxizität und Masern) H Mautner
39 Acidity of Urine in Various Diseases (Azidität des Harns in einigen Krankheiten) G Quagliariello and F Medina.
40 *Origin of Polycythemia K. Wakasugi
41 Placenta Praevia G Zinke (Cincinnati)
42 Carbon Dioxid Snow in Skin Disease (Vorrichtungen für die Gewinnung fester Kohlensäure zur Behandlung von Erkrankungen der Haut) H L. Heusner
43 *Simple Test for Hemin in the Blood (Vereinfachung der Häminkrystallprobe) Nippe
44 *Cancer in Children (Maligne Tumoren im Kindesalter) W Usener

37 **Traumatic Exophthalmic Goiter**—Dyrenfurth reports three cases of exophthalmic goiter developing after an accident In two cases a predisposition was evident, with stigmata of hysteria, these cases sustain the general assumption that when exophthalmic goiter develops *after a trauma*, the individuals were not previously entirely sound In the third case, however, a man in apparently perfect health was involved in an automobile street car accident, and two or three weeks after the physical pain had subsided, nervous symptoms developed and, six months later, symptoms of exophthalmic goiter It is a question whether the physical or psychic shock was the predominant factor The experiences to date with exophthalmic goiter of traumatic origin do not encourage the hope of recovery from operative measures Operations of various kinds which benefit under other conditions seem to do little good on patients suffering from the effects of an accident He has advised an operation on the thyroid in these cases, but doubts whether this will attack the evil at its root The fact that a trauma may entail exophthalmic goiter seems rather to support the assumption that the disturbed functioning of other glands as well as of the thyroid is of causal importance Every hypothesis of defective functioning of any glands is based on the disturbance in the innervation of the glands, and this again sustains the conception of the causal importance of the psychic trauma in such cases

38 **Toxicity of the Urine in Measles, Etc.**—Mautner reports ten cases in which the toxicity of the urine was tested, the results showing that abnormally high toxic power is not peculiar to measles, but may be encountered in diphtheria, scarlet fever, peritonitis and other affections, as well as in the healthy under certain conditions

40 **Polycythemia**—Wakasugi reports a case of polycythemia in which necropsy showed abnormal proliferation of the red bone marrow as the only probable cause for the polycythemia These findings confirm those reported in the ten other cases with post mortem findings on record

43 **Test for Hemin**—Nippe states that the crystals of hemin develop beautifully when the specimen of blood is mixed with a few drops of a solution of 0 1 gm each of potassium bromid, iodid and chlorid in 100 gm of acetic acid This durable solution shows up the crystals even in putrefied blood and in blood mixed with rust and long exposed to the weather The specimen on the slide is warmed until it bubbles, when the crystals form at once The excess of fluid is then taken up with blotting paper and the crystals mounted in Canada balsam without removing the cover glass

44 **Cancer in Children.**—Usener reports a round celled sarcoma of the clavicle in a boy of 8, a sarcoma of the right kidney in a girl over 4, a sarcoma in the abdominal wall in a girl of 13, and a sarcoma of the jejunum in a boy of 9 These malignant tumors formed 2 3 per cent of 173 tumors of various kinds encountered in two recent years at the Leipsic children's hospital It is remarkable that kidney cancer generally occurs at such an early age Monti found forty four under 5 in his fifty five cases, and Steffen 194 in his 222 cases Only ten of the eighty eight operative cases had a permanently favorable outcome, the other children succumbing to the operation as in the case described The cancer in the abdominal wall seems to be the only case of the kind on record, Steffen has reported two cases in infants, probably congenital, and the tumor was in the subcutaneous adipose tissue on the extremities in these cases The boy of 9 was cured by removal of the round celled sarcoma in the jejunum The prognosis of these cases is bad on account of the early metastasis Of the thirteen known to date, the patients were all boys but one An operation was done in three cases, but the one here reported is the only one with a favorable outcome, and for this appendicitis was responsible This compelled operative treatment, and during the operation the invaginated cancer was discovered The condition would probably have continued a long time without much disturbance if it had not been for the casual discovery during the operation on the appendix In all the other cases the intestinal sarcoma was practically inoperable when first discovered, and metastasis soon followed

Medizinische Klinik, Berlin

November 24 VIII No 47 pp 1893 1930 and Supplement

45 *Typhoid (Abdominaltyphus) H Hochhaus
46 Vasomotor Trophic Neuroses (Rolle des vegetativen Systems in der Pathologie der vasomotorisch trophischen Neurosen) R Cassirer
47 *Clinical Research on 1 400 Healthy Persons (Einiges über Albuminurie Pulsfrequenz Kniereflex vasomotorisches Nachröten Augen Zungen Händezittern Mac Burneyschen und Erbschen Druckpunkt, Mastodynie, Ovarie nach Untersuchungen an Gesunden) O Schellong
48 The Blood in Potassium Chlorate Poisoning (Zur Hämatologie der Kalichloricumvergiftung) F Gaisböck
49 *Treatment of Obesity (Einfache Methode der Bekämpfung der Fettleibigkeit.) A. Galisch
50 The Build of the Thorax and Pulmonary Tuberculosis (Thoraxbau und Tuberkulöse Lungenphthise.) C Hart.

45 **Typhoid.**—Hochhaus reports some unusual and puzzling cases, among them that of a young woman suspected of typhoid but all the signs were negative and the symptoms indicated merely a pyelocystitis, typhoid bacilli were found in pure culture in the urine and the usual symptoms developed after a time In a case recently reported by Jores a middle aged man succumbed to fulminating sepsis, even at necropsy nothing characteristic of typhoid was found, but the blood in the heart was swarming with typhoid bacilli Hochhaus suggests that fulminating sepsis of this kind might occur in an old typhoid bacilli carrier, and that typhoid and paratyphoid infections might occur together from new auto infection The low leukocyte count, retarded pulse and diazo are instructive differential points for typhoid In prophylaxis he calls attention to Perl's recent finding that typhoid bacilli are found on the teeth and tonsils late into convalescence Hochhaus' experience confirms the advantage of strict dieting for three weeks but then feeding soft foods more abundantly than has hitherto been the rule Meat had better be avoided until the temperature is permanently normal The newly acquired knowledge in regard to the distribution of the bacilli explains the lack of effective action from calomel, etc He adds that there does not seem to be much prospect for serotherapy of typhoid, as Pfeiffer has recently reiterated

47 **Clinical Tests on the Healthy**—Schellong tabulates his findings on examination of 1,400 presumably healthy persons applying for positions in the postal and telegraph service during a period of twelve years Albumin was found on boiling the urine in only 4.5 per cent of 1,400 men, confirming the rarity of albuminuria in the healthy The pulse was found 88 or over in 35 7 per cent of 1,000 male and female candidates, 96 and over in 22 per cent , 100 and over in 14.5 and 108 to 120 in 6 7 per cent , the women and most robust men having the fastest pulse The knee jerk was exaggerated in 85 per cent of 500 candidates, tremor of the tongue was evident in 33 per cent of 219, of the closed eyelids in 70 per cent of 240 examined, and tremor of the spread fingers of the extended right arm in 26 per cent of 217 examined McBurney's point was tender in only six of 500 examined The relative frequency of these nervous phenomena in the healthy persons examined shows that they must not be regarded as testifying to neurasthenia, hysteria or a traumatic neurosis in clinical cases, they are all within the range of the physiologic reactions of the nervous system Congestion and tenderness of the ovary and neuralgia of the mammary gland, on the other hand, were conspicuous by their absence in the hundreds of women examined The least nervous excitability was found in the persons whose previous occupation had kept them in the open air The number of seconds that elapse before redness develops in the skin after a line has been drawn on it with the finger, is a useful test of the vasomotor excitability, as also Steinert's definition of the knee jerk, namely, only that in which the pronounced reflex action follows the blow on the patella or tibia, not on the quadriceps tendon

49 **Treatment of Obesity**—Galisch has been very successful in reduci [illegible] the weight of his over corpulent patients by the one si [illegible] the a [illegible] ood taken after mid [illegible] at night to [illegible] breakfast [illegible] ffee or [illegible] t [illegible] and [illegible] od

taken up to noon. All his patients lost one or two pounds a week on this restriction of food after the noon meal, and all thrived on it

61 Technics for Examination of Cerebrospinal Fluid in Syphilis G L. Dreyfus
62 Retention of Urine from Bladder Tumors (Vesikale Harnstauung bei zottigen Blasengeschwülsten) O Zuckerkandl

51 **Nerve Blocking for Local Anesthesia** —Perthes has found that it is possible to determine whether the cannula is in direct contact with the nerve by sending a minimal electric current through the cannula insulated except at the tip A slight twitching follows in the muscle fibers innervated directly by the nerve, and this shows the exact moment when to inject the anesthetic The stimulation is too slight to cause pain, he gives a sedative before local anesthesia to keep the patient in a twilight hazy condition although still able to respond to appeals

54 **Neutral Red Reaction in Milk** —Moro states that a 1 per cent solution of neutral red turns human milk yellow and cow s milk purple One drop of the stain on a teaspoonful of drawn breast milk changes the tint to a reddish purple at once if the human milk has been kept too long and is thus unfit for use

56 **Salt in Prophylaxis of Anaphylactic Shock.**—Langer some time ago announced that the action of morphin was attenuated by ingestion of a strong salt solution He found this same mitigating action evident in guinea pigs treated with alien serum and then given strong salt solution by the mouth five minutes before the injection of serum was repeated Further experiments showed that this same protection against anaphylaxis could be attained by a course of small amounts of salt taken by the mouth These results suggest the application to man of this method of protecting against anaphylaxis by prolonged administration of salt in amounts too small to induce an appreciable reaction A connection between ingestion of salt and anaphylaxis is suggested by Heilner's experiments although in an opposite direction He found that injection of a hypertonic salt solution in serum treated animals, elicited phenomena of anaphylaxis just like those of an anaphylaxis inducing second injection of the serum

60 **Artificial Respiration Table** —Lewin gives an illustrated description of a folding portable table apparatus on which the individual to be resuscitated is fastened and with which it is possible to combine all the improved methods for artificial respiration including application of the principle of Schultze's swinging The apparatus is said to work so simply and easily that one person alone can manage it A similar table on a smaller scale would prove useful in reviving infants born asphyxiated

64 *Artificial Pneumothorax in Pulmonary Tuberculosis C Saugman
65 Calculus in Prostate (Om prostatasten.) G Naumann (Fall af prostatasten) K. Belfrage

64 **Artificial Pneumothorax in Treatment of Pulmonary Tuberculosis**—Saugman remarks that this unfortunate name has probably deterred some from adopting this method of treatment as the mere idea of a pneumothorax conjures up such dangers He has applied it in the last five years in 104 cases but found conditions in thirty one cases (30 per cent.) preventing effectual compression of the lung This percentage of failures is much larger, he adds, than in the American reports, probably because in America the procedure is applied before the disease has reached such advanced stages as in his material In his entire series of 2,100 injections of nitrogen he has had only one fatality, his ninety eighth patient, and important lessons were learned from this case The patient was a young man who dreaded the procedure intensely The puncture pierced only the chest wall and no gas could be injected Repeating the puncture it proved possible to inject 2 c c of the nitrogen until the manometer showed a slight negative pressure during respiration After waiting for eight or ten minutes the cannula was introduced for the third time When the manometer showed slight negative pressure the flow of gas was arrested The young man suddenly collapsed, with signs of heart failure after vomiting copiously he ceased to breathe There was no electric current available, but all other means of stimulation were tried in vain, including massage of the heart Necropsy failed to disclose any cause for the fatality, no lacerated vessel could be found so that air embolism can probably be excluded. The findings were like those in a fatal chloroform accident Everything pointed to reflex paralysis of the heart from pleura shock The case teaches that the injection of gas should not be made soon after eating, and that the reflex excitability should be reduced by a preliminary injection of morphin, and further, that not more than one puncture should be made at one sitting Saugman has often made one, two, three or four punctures at one sitting without any inconvenience, but he is convinced that this young man would not have died thus if only one puncture had been made that day Another lesson taught by the case is to have ether camphor and digitalis at hand and also an electric induction current The possibility of a fatality must always be borne in mind, as with general anesthesia, but the same as with this, fatalities are so rare that the fear of them should not deter from the use of this valuable measure Aside from this fatality the only by effects noted were in a few cases transient dizziness, seeing black, or distress, or brief paresis in one arm, with brief clonic contraction A few patients with a habit of swooning fainted but none lost consciousness and there were no disturbances in the pupil or field of vision In two cases there was a suspicion of air embolism, the nitrogen was being injected under high pressure and a sudden movement of the patient may have ruptured an adhesion and thus torn a vessel in it, but the immediate *subsidence of the symptoms apparently excluded the assumption* of air embolism He tabulates the details under sixteen headings of the entire 104 cases especially the signs indicating the possibility of effectual compression They are far from conclusive to date and further research is urgently needed on means to determine beforehand whether the pleural cavity is open or not Even Litten's diaphragm phenomenon sometimes proved misleading In seventy two of the total 104 patients effectual compression was realized and effects were obtained he says, surpassing those possible with any other method especially in a group of thirty five pure cases, free from complications Of four patients with temperature over 39 C three became entirely afebrile, five of seven with temperature of 38 to 39 C, and five of six with subfebrile temperature, while nine with occasional febrile periods have been entirely free from them since In all of this group of thirty five the tuberculous process was severe, involving the entire lung with much destruction of tissue in some, and the other lung showed some involvement in a few instances, in three of half of the lung and more He prefers puncture to an incision, citing four cases in eighty on record in which fatal infection developed after the incision technic for pneumothorax He thinks this positive danger far outweighs the hypothetical danger of air embolism with the puncture technic.

Pennsylvania June Examination Q

The following are the questions asked by the Bureau of Medical Education and Licensure of Pennsylvania, at the examination held June 24 to 26 inclusive, 1912 It is interesting to note that closely related subjects have been combined for the examinations held in each half day session This differs quite markedly from the usual procedure The arrangement of subjects in the five half day sessions and the questions asked are as follows

FIRST HALF DAY SESSION

PHYSIOLOGY PATHOLOGY AND BACTERIOLOGY

1 Given an acute attack of peritonitis due to perforating appendicitis, state the pathologic conditions that may be present and give the determining cause together with a method of demonstrating this cause

2 In acute lobar pneumonia (croupous pneumonia) detail the local conditions the determining cause of these conditions and state briefly their effect on the normal function of the lungs as well as on metabolism

3 Discuss briefly the lesions in the diffuse form of arteriosclerosis both in the blood vessels and in important associated organs Explain the effect on the function of these organs

4 Describe two lesions of the liver that will cause lessening of the supply of bile and discuss in detail the effect of this loss

5 Detail the lesions in typhoid fever describe the determining cause and explain the sources of elimination

6 Given a patient with an incipient tuberculosis of the lungs explain the local lesions describe at least two laboratory methods by which the diagnosis may be verified and discuss in detail each method

7 Describe a method pursued in the preparation of diphtheria antitoxin and give the reasons for the various steps

8 Describe the lesions name the causes and outline the technic of a method of demonstrating the variety of ophthalmia neonatorum

9 In carcinoma of the female breast, name the varieties describe the gross appearance of each and enumerate the avenues and usual points of metastasis

10 Enumerate four of the usual pathologic lesions capable of causing hematuria describe two of these conditions (one of cystic, the other of renal origin) with a method of demonstrating each in life

SECOND HALF DAY SESSION

SYMPTOMATOLOGY DIAGNOSIS TOXICOLOGY AND MEDICAL JURISPRUDENCE

1 State the local and the constitutional symptoms of follicular tonsillitis and differentiate it from diphtheria

2 Enumerate the diagnostic symptoms of angina pectoris and name other diseases that resemble it, stating their points of difference

3 Enumerate the symptoms and physical signs diagnostic of lobar pneumonia and differentiate it from subacute pleurisy with effusion

4 Describe in detail the symptoms of scarlatina and differentiate this disease from measles

5 Given a patient brought into the hospital unconscious with a history of having fallen in the street name four diseases which might exist and give the differential diagnosis

6 State the diagnostic symptoms of acute miliary tuberculosis name another disease with which it may be mistaken and differentiate the two diseases

7 What is ptomain poisoning? Enumerate the diagnostic symptoms of same and state other conditions that may resemble it

8 State the symptoms of acute anterior poliomyelitis in its different stages and differentiate it from neuritis

9 Give the symptoms of acute (fatal) arsenical poisoning and enumerate a legal question which must be considered by the physician under these circumstances

10 What medicolegal reasons would justify a physician in terminating a pregnancy? What steps should be taken prior to this action?

THIRD HALF DAY SESSION

OBSTETRICS AND GYNECOLOGY HYGIENE AND PREVENTIVE MEDICINE

1 Name the common abnormalities of the breasts after confinement their causes prevention local and hygienic treatment

2 What methods would you adopt in order to relieve the vomiting of pregnancy and on what theory would you use the various methods mentioned?

3 What symptoms would lead you to the apprehension of an oncoming attack of eclampsia before the convulsions set in? What is its treatment both before and after the convulsions?

4 What are the dangers of abortion (miscarriage)? If abortion occurs how are these dangers avoided and if they are not avoided how are they overcome?

5 What is the significance of excessive menstrual bleeding intermenstrual bleeding entire absence of bleeding?

6 Name the more usual bacteria which cause puerperal septicemia together with the methods of their introduction into the birth canal the results of their presence there and the prevention of these results

7 Name four abdominal enlargements which might be mistaken for pregnancy and differentiate them from pregnancy

8 Outline the essential conditions surrounding a safe and healthful supply of drinking water If unsafe how may the water be rendered safe for use?

9 During an epidemic of typhoid fever what precautions are necessary both as to the immediate family and as to the community at large?

10 In inspecting a house as to its plumbing what are the essential points to establish?

FOURTH HALF DAY SESSION

ANATOMY AND SURGERY

1 Enumerate the lesions to be considered resulting from a severe blow on the nose and give the method of treatment of any two forms of injury selected

2 Outline the essentials of a good amputation describe any one major amputation giving the surgical anatomy of the part selected

3 Enumerate five of the more usual conditions capable of causing peritonitis describe an operation that might be required for any one condition selected

4 What conditions would warrant the enucleation of an eye? Describe an operation for the same.

5 In severe injury about the ankle joint enumerate what possible lesions should be considered

6 Describe the technic of intravenous infusion state the veins accessible for infusion and how to locate each

7 What surgical conditions must be considered in retention of urine? Outline an operation for the correction of any one condition selected with the reasons for selecting this

8 State the usual position of the fragments in an oblique fracture of the lower third of the femur and the muscular control of the fragments

9 State possible lines of transmission of infection in palmar abscess and give the external landmarks for the location of the palmar arches

10 What symptoms and conditions referable to the gall bladder or liver would call for operative interference?

FIFTH HALF DAY SESSION

MATERIA MEDICA THERAPEUTICS

1 (a) What is ergot? (b) give its official name (c) enumerate the official preparations, (d) give dose of each (e) what are its most pronounced physical actions?

2 Write a prescription in the metric system with the directions for administration containing a nitrite and state what effect you would aim to produce another prescription containing an ammoniacal heart stimulant and a third containing a hydragogue cathartic in pill form

3 From what class of organic substances are acetanilidum and acetphenetidinum obtained? What is their general physiologic action? What is the action of most of this class of drugs on the blood? Give the dose of the two above named How are they excreted?

4 Give the official name of five salts or other preparations of mercury and state the therapeutic indications of each

5 How would you treat a case of typhoid fever together with the more important complications? Give dose and frequency of administration of each remedy you would use in this disease together with reasons for its employment.

CHEMISTRY

1 What is the chemical reaction of blood? To what is it due? What is hemoglobin? Oxyhemoglobin? Methemaglobin?

2 Describe a quantitative test for urea in urine What is the usual composition of biliary calculi? Describe their physical appearance In what manner do they originate?

3 What is chlorin? How does it chiefly occur in nature? Describe its physical properties In what form is it found as a component part of the human body? Mixed in equal proportions with hydrogen what chemical action takes place?

4 Differentiate between human and cow s milk as to percentage of water proteid matter sugar fat and ash

5 Describe the technic of Fehling's test for sugar in urine In case the test proves positive what is the visible evidence thereof and on what chemical basis does it rest?

Book Notices

ARTHRITIS A Study of the Inflammatory Diseases of Joints By Peter Daniel F R.C S Senior Surgeon Metropolitan Hospital London Edited by James Cantlie M A M.B No 8 the Medico-Chirurgical Series Cloth. Price, $4 Pp 515 New York William Wood & Co 1911

This book abounds in personal experiences, and represents the author's views and opinions based on knowledge and observation He is emphatic in his statement that "except as a result of trauma, arthritis is only a symptom of a disease whose real nidus is in some distant part of the body" Nor would he differentiate synovitis from arthritis, because "only a very short acute inflammation can possibly involve the synovial membrane alone" He also emphasizes the fact that the arthritis may be secondary to a disease in some other part of the body even years after the subsidence of the primary infection Sepsis and arthritis—this is the sequence of events Daniel has found that by far the commonest source of arthritis is sepsis in the oral cavity—a fact to which all experienced clinicians now subscribe As for the toxic arthritis, he suspects a microorganism as being the real cause of the trouble in every case

Considerable space is devoted to a discussion on rheumatoid arthritis, which the author believes to be caused by a multiplicity of bacterial processes, foremost among these being genital infection The treatment advocated in all these lesions is one which combats the primary cause of the trouble—the original infection—and which prevents local deformity and destruction of tissue Specific treatment of the local trouble, which fails to take into account the primary nidus, is condemned, and rightly so The trouble is not, Daniel says, a local one The joint symptoms are merely a local manifestation of a systemic affection or a localized infection in some other part of the body Therefore, they combat infection and prevent destruction of tissue He employs, as a routine, Bier's hyperemia, aspiration of cavities containing pus, injection of iodoform and glycerin emulsion, and extension The latter is emphasized as being the only effective means to prevent deformity

The book is well written and contains a mine of information on an exceedingly important subject

COMMON DISORDERS AND DISEASES OF CHILDHOOD By George Frederic Still M A M D F R C P Professor of Diseases of Children King's College, London Second Edition Cloth Price $5 50 Pp 813 with illustrations Oxford Medical Publications London Henry Frowde 1912

Since this book was reviewed in THE JOURNAL in 1909 changes and additions have been made to bring the work up to conform to the present understanding of the various subjects in pediatrics Among the additions in this edition are sections on enlarged tonsils and adenoids, epilepsy, asthma and hydrocephalus The sections on infantile paralysis and congenital syphilis have been revised to correspond with later information on those subjects The work still retains its former character of a record chiefly of the personal experiences and opinions of the author, who is well qualified to impart most valuable information on the common disorders and diseases of childhood

THE CHEMICAL CONSTITUTION OF THE PROTEINS By R H A Plimmer D Sc Assistant Professor of Physiologic Chemistry University College London Monographs on Biochemistry Second Edition Two Parts. Part I—Analysis Cloth. Price 5 shillings 6 pence New York Longmans Green & Co 1912

THE PHYSIOLOGY OF PROTEIN METABOLISM By E P Cathcart M D D Sc Grieve Lecturer on Chemical Physiology in the University of Glasgow Monographs on Biochemistry Cloth Price $1 25 net Pp 142 New York Longmans Green & Co 1912

The monographs of this series which have so far appeared entirely fulfil the hopes with which the outcome of the enterprise was awaited As we have stated before, this seems to be the best way yet devised for publishing such rapidly developing subjects as biologic chemistry The publication of small and inexpensive monographs, each written by a man specializing in the field he covers, permits accurate presentation and frequent revision We note with pleasure that some of these monographs are already appearing in a second edition While all are of extreme value to specialists in biologic chemistry and the many related subjects, several are also of great interest to the progressive physician, and none more so than Cathcart's "Physiology of Protein Metabolism" We can strongly recommend to any physician who wishes to acquaint himself with the modern developments in our knowledge of protein metabolism, with all that this subject means for nutrition and dietetics, a careful reading of this monograph In it will be found as careful, accurate and interesting an exposition as can be desired Plimmer's review of the chemical composition of the proteins and the methods of analysis used in their study is of more direct interest to the biologic chemist than to the physician, but to the latter it should be of value as a reference work to elucidate the terms of protein chemistry which are now so frequently met in medical literature

PRIMARY MALIGNANT GROWTHS OF THE LUNGS AND BRONCHI A Pathologic and Clinical Study By I Adler A M M D, Professor Emeritus at the New York Polyclinic. Cloth Price $4 net Pp 325 with 17 illustrations New York Longmans Green & Co 1912.

Primary cancer of the lung is usually regarded as one of the very rare forms of cancer, but the number of cases being recorded indicates that after all it perhaps is not so rare In his monograph Adler collects reports of 374 cases of primary carcinoma, ninety cases of sarcoma and about 100 other cases in which the diagnosis was not conclusive The anatomic features and the clinical manifestations are discussed fully and interestingly Surely any physician who reads carefully the hundred odd pages devoted to this discussion will be better prepared to detect early the existence of cancer of the lung So far the treatment of primary cancer of the lung has been practically only symptomatic and for the purpose of relief, any hope of cure being regarded as out of the question It has been asserted that lung cancer is unique because absolutely beyond the reach of the surgeon Even if surgery might become better equal to the task it would be of no use because the diagnosis cannot be made early enough In the meantime the technic of lung surgery has developed rapidly and in actual cases of lung cancer there has been operation, with relief to the patient and possibly lengthening of life Adler emphasizes strongly the principle that with this advance in surgery, which is likely to continue, added responsibility is placed on the physician as the only hope lies in early diagnosis He should realize that the disease is not so infrequent but that he may meet a case any day Adler recommends exploratory thoracotomy in cases suspected to be lung cancer but not susceptible of definite diagnosis This operation may prove of service also in relieving distressing symptoms

SEXUAL IMPOTENCE By Victor G Vecki M D Consulting Genito Urinary Surgeon to the Mount Zion Hospital San Francisco Fourth Edition Cloth Price $2 25 Pp 394 Philadelphia W B Saunders Company 1912

The fourth edition of this standard monograph on impotence is much enlarged and contains many facts that have been brought out since the third edition was published The author considers impotence as a symptom and discusses thoroughly its etiology pathology, symptomatology and treatment There is an exhaustive chapter on prophylaxis, and finally a review is given of all known methods of treating impotence These are thoroughly discussed, and the experience of the author with each of these methods is reported Any physician who will spend the time to read Dr Vecki's book will learn a great deal about this common, complex and obscure symptom, impotence

DIAGNOSE DER SIMULATION NERVÖSER SYMPTOME Ein Lehrbuch für den Praktiker By Dr Siegmund Erben Vienna Paper Price, $2 15 Pp 194 with 24 illustrations New York Rebman Company 1912.

This short compendium on the diagnosis of simulated nervous symptoms is complete in itself and calculated to warn the practitioner of the numerous errors into which he may fall when examining for simulation The work can be recommended especially to those who are frequently called on to testify in the courts in questions involving nervous diseases of a functional character, sustained through railway or other accidents An English translation would be welcome

EXPLANATION OF THE USE OF THE INDEX

This is an index not only to the reading matter in THE JOURNAL, but also to original articles in the principal medical periodicals of this and other countries The reading matter appearing in THE JOURNAL is distinguished by the use of black-faced numerals

The letters used to explain in which department the matter indexed appears are as follows "E," Editorial, "C," Correspondence, "T," Therapeutics, "Ml," Medicolegal, "P," Propaganda for Reform, "ME," Medical Economics, "ab," abstract, the star (*) indicates an "Original Article" in THE JOURNAL.

This is a subject index and one should, therefore, look for the chief word, with the following exceptions "Deaths" and "Society Proceedings" are indexed under these titles at the end of the letters "D" and "S" Matter pertaining to the Association is indexed under "American Medical Association"

All matter is indexed under the most important word of the heading used in THE JOURNAL, and also under the subject heading For instance, abscess of the brain will be found under "abscess," as well as under "brain" Such titles as "ocular manifestations, etc" have been indexed under "Eye" Cross references have been liberally used

The figures in parentheses refer to the paragraph, the number following to the page in THE JOURNAL, for example

> ABDOMEN gun shot wound complicated by 22 intestinal perforations ***1886**

This reference is to an original article in THE JOURNAL as shown both by the star and by the black faced numerals indicating the page

> ACID solution for examination of cerebrospinal fluid preparation of **960**

This reference, as indicated by the black faced figures, is also in THE JOURNAL, and on turning to page 960 we find an answer to a question in the Department of Queries and Minor Notes

> ABDOMEN echinococcosis of (5) **1222**—ab

In this one, the page number, being in black faced type, shows that the matter is discussed in THE JOURNAL, "ab" indicating that it is an abstract Turning to page 1222, we find (5) refers to an article by T S Tirumurti in the *Indian Medical Gazette*, August.

> ABDOMEN adhesions preadhesions and postadhesion in pelvis and (52) 2003

The fact that in this last reference the page is given in ordinary type indicates that only the title of the article is given Turning to page 2003 we find that the numeral (52) refers to a paper on that subject by F E Walker which appeared in the *Journal of the Iowa State Medical Society*, November

In the AUTHOR'S INDEX are the names of the authors of articles which have appeared in THE JOURNAL of the American Medical Association and of articles that have been listed from week to week in the Department of Current Medical Literature as having appeared in other journals The black faced numerals indicate that the article is in THE JOURNAL, either in full or in abstract The star (*) preceding the page number, indicates an original article
